CONTENTS

EXECUTIVE SUMMARY

In 1991, National Marine Fisheries Service (NMFS) research addressed three areas related to smolt transportation. The first was an ongoing evaluation of smolt transportation from Lower Granite and McNary Dams. The second was a pilot study to examine the feasibility of using passive integrated transponder (PIT) tags to evaluate transportation of wild spring/summer chinook salmon. The third and final area was an evaluation of the PIT-tag detection/diversion system at Lower Granite Dam.

1. Transportation Studies

Drought conditions in the Snake River Basin again precluded marking of spring/summer chinook salmon and steelhead smolts for the final year of a 3-year reevaluation of transportation from Lower Granite Dam. Marking of juvenile fall and spring/summer chinook salmon for a similar 3-year study at McNary Dam was completed in 1988.

Adult recovery efforts continued for the above studies and for groups of smolts marked for the transport index at Lower Granite Dam in the 1987 and 1990 drought years. Adult returns of spring/summer chinook salmon and steelhead for the 1987 barge transport index are now complete. Returns for spring/summer chinook salmon were similar to returns for other marked and transported groups of the same stock in recent years. For steelhead, adult returns were similar to returns for recent years even though low flows and warm water in the Snake River in fall 1988 likely reduced the return of 1-ocean adults. Few adults of either species have returned from the

transport and control groups marked at Lower Granite Dam in 1989, probably as a result of poor ocean survival. However, returns are higher for the transported groups of both species.

For the McNary Dam studies, adult returns of transport and control groups of spring/summer chinook salmon marked in 1987 are complete. More adults from transported than control groups were recovered at all sample locations, but the results were inconclusive due to insufficient adult returns. Adult returns for the 1988 study year are incomplete, but the preliminary return rates are similar to those of the 1987 study. For fall chinook salmon, returns of transport and control groups marked from 1986-88 are incomplete. So far, returns for all study years to all locations strongly favor the transported groups.

2. Pilot Study of PIT Tag Feasibility in Transportation Studies

We completed the final year of a 3-year pilot study to examine the feasibility of utilizing PIT tags to evaluate transportation of wild yearling chinook salmon smolts in the Snake River. These fish were PIT tagged as parr in their natal streams during the summer of 1990 and intercepted as smolts the following spring at the collector dams for the transportation program. Hatchery fish were also included in the study. As during the previous 2 years, mortalities associated with the collection and tagging of wild fish were exceptionally low. Recovery rates for these fish at the dams the following spring were improved over those of the previous 2 years, but were still lower than originally expected. The outmigration timing was later than during the previous 2 years for all wild stocks, but similar to the previous 2 years for hatchery stocks. As

during the previous 2 years, outmigration periods for wild fish from individual streams were protracted and highly variable within and among years. In all years, hatchery stock migration periods were compressed and consistent.

3. Assessment of PIT-tag Detection/Diversion System

We completed the third year of evaluation of a PIT-tag detection/diversion system at Lower Granite Dam. Recommended modifications to the system, based on results from the previous 2 years of evaluation, produced the desired results. The efficiency of the system varied proportionally to the facility counts. When facility counts were below 5,000 fish per hour, 0.43 untagged fish were diverted per PIT-tag diversion cycle. When the facility counts were between 30,000 and 35,000 fish per hour, 3.19 untagged fish were diverted per cycle. In contrast to previous results, the abundance of steelhead in the system appeared to have no influence on the efficiency of the system. These results indicate that the system is ready for use in monitoring or research programs.

TRANSPORTATION STUDIES, LOWER GRANITE AND MCNARY DAMS

Introduction

To index the relative success of the barge transportation program conducted annually since 1981 by the U.S. Army Corps of Engineers (COE), spring/summer chinook salmon smolts were marked at Lower Granite Dam in 1983, 1984, and 1985 and steelhead smolts were marked in 1984 and 1985. No paired control groups of either species were marked during any of the above years. The 1985 smolt marking operations were conducted by the Fish Passage Center (formerly the Water Budget Center). Therefore, data on these releases were not included in any of the National Marine Fisheries Service (NMFS) annual reports. Final adult returns for the 1983 and 1984 study years were reported in Harmon et al. (1989), and final adult returns for the 1985 study year were reported in Matthews et al. (1990). By 1985, preliminary adult returns from these marking efforts indicated that survival of marked/transported smolts had improved considerably compared to returns from the 1976-80 study years (Park et al. 1986). We believe a combination of factors is responsible for the observed increase in smolt to adult survival. These factors include, but may not be limited to, major improvements in transport collection facilities, improved fish quality, and greatly improved fish handling/marking techniques.

In 1986, a new 3-year transportation study was initiated on spring/summer chinook salmon and steelhead at Lower Granite Dam and spring/summer and fall chinook salmon at McNary Dam. The primary goal of the study was to reevaluate transportation of smolts around dams utilizing state of the art collection/transport and

handling/marking techniques. At McNary Dam, we marked transport and control groups of spring/summer and fall chinook salmon for three consecutive years (1986-88). At Lower Granite Dam, we marked transport and control groups of spring/summer chinook salmon and steelhead in 1986. However, drought conditions caused low river flows and interrupted the marking schedule in 1987, 1988, 1990, and 1991. We marked transport and control groups of both species in 1986 and 1989. In 1987 and 1990, we marked barge transport groups for indexing of both species. No marking was done in 1988 and 1991 due to the prolonged drought. Recovery of adults for most of these marking efforts is incomplete. However, adult returns for the 1986 study year at Lower Granite Dam are complete and were reported by Matthews et al. (1992).

To determine the hatchery/wild composition of the Snake River spring/summer chinook salmon population, NMFS and the Oregon Department of Fish and Wildlife began a study to examine scales on smolts and returning adults. In particular, the study was intended to examine the hatchery/wild composition of each marked group of smolts for the transportation study and, subsequently, to examine the scales of those returning as adults. Since drought conditions precluded marking of smolts for the 1991 study year, we sampled scales from adults returning from previous marking efforts and from the general population. Results of this effort are reported in Appendix 2 of this report.

Methods

General

Smolts at both dams were marked with CWTs and freeze brands during each year's outmigration, and either transported by barge for release below Bonneville Dam or released as controls below Little Goose or McNary Dams. Matthews et al. (1987) provides details on juvenile marking procedures.

Recovery of Adults and Data Analysis

Adults were recovered in each of 3 to 6 years (depending upon species and study site) following release as juveniles. Traps in fish ladders at Lower Granite and Priest Rapids Dams (for McNary Dam releases) were the primary recovery sites for spring/summer chinook salmon and steelhead. Ocean and river commercial fisheries were primary recovery sites for fall chinook salmon marked at McNary Dam. If recoveries were sufficient, trapping efficiencies were estimated for individual release lots by comparing the number of marked fish identified in a fish ladder trap to the total number of marked fish returning to the hatcheries and, when available, to tributary sport fisheries and natal spawning areas.

Evaluation of transportation was based upon recovery rates of adults and associated transport/control ratios (T/C) from fish marked as juveniles. A 95% confidence interval (CI) was used to test the null hypothesis: That the true transport to control ratio was equal to one (1). If the 95% CI did not include a ratio equal to one (1), then the null hypothesis was rejected. Beginning at Lower Granite Dam in 1989, the study design was adjusted to test a

T/C of 1.5 with a coefficient of variation of 10% for spring/summer chinook salmon and 7.5% for steelhead.

To normalize the distribution, the ratios were log transformed prior to CI construction. The endpoints of the CI were then back transformed to provide a nonsymmetric CI on the original scale. For analysis using total recoveries, the CI was calculated using both theoretical and empirical estimates of variance. The CI employing the empirical variance estimate was preferred.

The 95% CI using transformed data based on theoretical variance was:

$$\ln(T/C) \pm 1.96\sqrt{\frac{1}{n_t}+\frac{1}{n_c}-\frac{1}{N_t}-\frac{1}{N_c}}$$

The 95% CI back transformed to the original scale was:

$$\left(e^{\ln(T/C) - 1.96\sqrt{\frac{1}{n_t}+\frac{1}{n_c}-\frac{1}{N_t}-\frac{1}{N_c}}}, e^{\ln(T/C) + 1.96\sqrt{\frac{1}{n_t}+\frac{1}{n_c}-\frac{1}{N_t}-\frac{1}{N_c}}} \right)$$

The 95% CI using transformed data based on empirical variance was:

$$\ln(T/C) \pm t_{0.05}{}^{n-1}\ S.E.(\ln(T/C))$$

The 95% CI back transformed to the original scale was:

$$\left(e^{\ln(T/C) - t_{0.05}^{n-1} S.E.(\ln(T/C))} , e^{\ln(T/C) + t_{0.05}^{n-1} S.E.(\ln(T/C))} \right)$$

where,

T/C = overall transport recovery percentage divided by overall control recovery percentage

$S.E.$ = standard deviation of the r replicate ln(T/C)'s divided by $r^{1/2}$

n_t = total of transport recoveries

n_c = total of control recoveries

N_t = total of transport releases

N_c = total of control releases

t = the t probability for a two-sided significance level α=0.05 and n-1 degrees of freedom

1.96 = the normal probability for a two-sided α = 0.05

Results and Discussion

Adult Recoveries for Lower Granite Dam Studies

Spring/summer chinook salmon--Adult recoveries from 1987 Lower Granite Dam smolt releases of the barge transport index group are complete (Table 1 and Appendix Tables 1.0 through 1.11). We recovered 91 fish at Lower Granite Dam (0.18% of releases) and 118 fish at all recovery sites combined (0.24% of releases). These adult returns are similar to the returns of marked groups of smolts transported by barge from the dam in 1984, 1985, and 1986, when observed adult returns at the dam ranged between 0.16 and 0.22% of the smolt releases.

Table 1.--Summary of recovered adult spring/summer chinook salmon marked as juveniles at Lower Granite Dam in 1987 and transported to below Bonneville Dam by barge (recoveries through July 1991). Numbers in parentheses represent adults that were jaw tagged at the dam and subsequently recovered upstream.

Number released	Ocean-age	Observed adult returns: Ocean fishery	Bonneville Dam	Indian fishery	River fishery	Lower Granite Dam N	Lower Granite Dam %	Hatcheries	Stream surveys	Total N	Total %
50,207	1	2	0	0	1	12 (1)	0.02	0	0	14	0.03
	2	0	9 (5)	2	1	66 (19)	0.13	35	0	89	0.18
	3	0	1 (1)	2	0	13 (2)	0.03	1	1	15	0.03
	Total	2	10 (6)	4	2	91 (22)	0.18	36	1	118	0.24

Recoveries of adults from transport and control groups of smolts marked at Lower Granite Dam in 1989 are preliminary (Table 2 and Appendix Tables 2.0 through 3.12). To date, returns to Lower Granite Dam are much lower than expected with 26 (0.03% of releases) transports and 17 (0.02% of releases) controls. These recoveries include 1- and 2-ocean returns with 3-ocean fish due to return in spring 1992. Adult returns to the Snake River from the 1989 smolt outmigration were also poor for general populations of both spring/summer chinook salmon and steelhead. Therefore, we are unsure if the addition of 3-ocean recoveries will provide sufficient adult return information to provide a precise T/C estimate for this study year.

During spring 1990, an unusually high occurrence of teeth marks, resulting from attacks by marine mammals, was documented on spring/summer chinook salmon at Lower Granite Dam (Matthews et al. 1992). In spring 1991, we collected data on 1,325 returning spring/summer chinook salmon throughout the adult migration (Table 3). Overall incidence of marine mammal teeth marks was 14.0% (7.4% descaled and 6.6% flesh wounds) for 1991 as compared to 19.2% for a similar period during the previous year. Highest incidence occurred during the early portion of the migration and tapered off as the migration progressed. Impacts by marine mammals may further jeopardize salmon stocks already at low levels of abundance.

Steelhead--Adult returns for steelhead marked as smolts and released in 1987 as a barge transport index are complete (Table 4 and Appendix Tables 4.0 through 4.7). The total adult return from all age classes to the dam was 500 fish or 1.82% of the release.

Table 2.--Preliminary summary of recovered adult spring/summer chinook salmon marked as juveniles at Lower Granite Dam in 1989 (recoveries through July 1991). Controls were released below Little Goose Dam. Numbers in parentheses represent adults that were jaw tagged at the dam and subsequently recovered upstream.

	Total	10 (6)	3	132	500 (187)	1.82	64	516	1.87

However, nearly four times as many fish were recovered at the dam as 2-ocean fish in 1989 than as 1-ocean fish in 1988 (1.41 vs 0.37%, respectively). Normally, we would expect to recover nearly as many 1- as 2-ocean adults from a given smolt outmigration. It appears that 1-ocean adults encountered unfavorable conditions in the form of low river flows and high water temperatures while migrating upstream in fall 1988 (Matthews et al. 1992). These conditions likely caused delays in migration and high mortality in migrating adults of this age class. Conversely, 2-ocean adults returning in 1989 encountered higher flows and lower water temperatures, resulting in much improved returns. Similar differences were identified with returning adult steelhead marked in studies conducted during 1984-86 (Harmon et al. 1989, Matthews et al. 1990).

Adult returns of steelhead smolts marked for transportation research in 1989 are preliminary, as only 1-ocean adults have returned to date (Table 5 and Appendix Tables 5.0 through 6.5). Unfortunately, the preliminary returns are exceptionally poor. Only 33 adults (0.11% of the release) that were transported by barge and 34 adults (0.08% of the release) that were released as inriver controls returned to the dam as 1-ocean fish. The overall return of adults (56,979) in the general population at Lower Granite Dam in fall 1990 and spring 1991 was also low. Further, these returns were predominated by 2-ocean adults from the 1988 smolt outmigration, indicating a very poor return of 1-ocean fish from the 1989 outmigration. A similar pattern was observed for spring/summer chinook salmon from the 1989 smolt outmigration. Since river flows in spring 1989 were the highest of the past 5 years (1987-91) and

Table 5.--Preliminary summary of recovered adult steelhead marked as juveniles at Lower Granite Dam in 1989 (recoveries through July 1991). Controls were released below Little Goose Dam. Numbers in parentheses represent adults that were jaw tagged at the dam and subsequently recovered upstream.

Groups	Number released	Ocean-age	Observed adult returns: Bonneville Dam	Indian fishery	River fishery	Lower Granite Dam N	Lower Granite Dam %	Hatcheries	Total N	Total %
1989 Transport	30,116	1	0	2	3	33 (3)	0.11	0	35	0.12
1989 Control	42,259	1	1	2	3	34 (4)	0.08	1	37	0.09

only slightly below average for the past 20 years, survival in the estuary or ocean was presumably poor for 1989 outmigrants, regardless of transportation.

Adult Recoveries for McNary Dam Studies

Spring chinook salmon--Adult recovery efforts for transportation studies conducted at McNary Dam from 1986 through 1988 continue. Final returns for the 1986 study year were reported (Matthews et al. 1992) and were so few as to preclude statistical analysis. Recoveries from 1987 releases are complete, while additional recoveries from 1988 releases are expected in the coming months.

Adult returns for the 1987 study year, while poor, were improved over returns for the 1986 study year (Table 6 and Appendix Tables 7.0 through 8.8). Due to low recovery numbers, we calculated only theoretical CIs for the T/C estimates based on adult recoveries at Bonneville and Priest Rapids Dams, in the river commercial and Indian fisheries, and at hatcheries (Table 7). Both theoretical and emperical CIs were constructed for total combined recoveries. The T/Cs (95% CIs) ranged from 1.11 (0.56, 2.21) at Bonneville Dam to 7.50 (2.17, 25.89) in the river commercial fishery. Again, the imprecise results were due to the small numbers of adult recoveries. While the overall T/C of 1.63 indicated a benefit from transportation, the lower CI limit overlapped 1.00.

In summary, results of the 1987 study suggest a positive association between transportation and survival of spring chinook salmon from McNary Dam. However, confidence values around the T/C estimate were large. Therefore, any future testing should include

Priest Rapids Dam	1.88	(0.98, 3.52)	[a]
River fishery	7.50	(2.17, 25.89)	[a]
Indian fishery	1.05	(0.40, 2.77)	[a]
Hatcheries	2.12	(1.14, 3.95)	[a]
Combined	1.63	(1.18, 2.25)	(0.57, 4.63)

[a] Too few adult recoveries to estimate

greatly increased numbers of marked smolts to provide adequate adult recoveries for precise and conclusive results.

Adult returns from smolts marked at McNary Dam in 1988 are similar to the returns for 1987 study year (Table 6 and Appendix Tables 9.0 through 10.10). Recoveries are quite low so far, and when complete, it is likely the results will be comparable to the 1987 study. A total of 55 transport (0.11% of releases) and 62 control (0.08% of releases) returns have been documented to all recovery sites combined so far.

Fall chinook salmon--Adult returns from transport and control releases of juveniles marked at McNary Dam from 1986 through 1988 were monitored at Bonneville Dam, in the ocean, river, tribal fisheries, and at hatcheries. Returns to date are incomplete, but existing data are shown in Table 8 and Appendix Tables 11.0 through 16.5.

Preliminary recoveries of 1- to 4-ocean age adults from 1986 releases indicate substantial benefits for transported fish. A total of 416 transports (0.36% of the releases) and 159 controls (0.14% of the releases) have been recovered, resulting in a T/C of 2.60. As expected, most recoveries were from the ocean fisheries with substantial numbers recovered from the tribal fishery, as well as from hatcheries and at Bonneville Dam. We expect to recover a few 5-ocean adults next year in addition to receiving late data from the various fisheries.

Preliminary percentage returns of adults from 1987 marked fish are higher than for the 1986 study year for the same recovery period (Table 8). As with the 1986 releases, most recoveries have come

Table 8. --Preliminary summary of adult recoveries of fall chinook salmon marked as juveniles at McNary Dam from 1986 to 1988 (recoveries through July 1991).

Numbers in paranetheses are fish that were subsequently recaptured.

from the ocean fisheries. Furthermore, the overall T/C of 3.00 is higher than for the 1986 fish. Additional recoveries are expected in ensuing years.

Adult returns from 1988 juvenile releases are few to date, with only 11 transport and 8 control fish recaptured (Table 8). Many additional returns are expected within the next few years.

PILOT STUDY TO EXAMINE THE FEASIBILITY OF USING PIT TAGS TO EVALUATE TRANSPORTATION OF WILD CHINOOK SALMON SMOLTS

Introduction

The NMFS and COE conducted pilot studies in the summers of 1988 and 1989 with the primary objective of examining the feasibility of using PIT tags to evaluate transportation of yearling chinook salmon smolts. Both wild and hatchery-reared fish were included in these studies. During the first 2 years, we developed effective techniques for collecting and PIT tagging large numbers of wild parr in their natal streams with low mortality rates, observed detection rates much lower than expected for all PIT-tagged fish upon their arrival the following spring at the three collector dams, and determined that outmigration timing of yearling chinook salmon smolts through Lower Granite Dam differs considerably between hatchery and wild fish.

In the summer of 1990, we began the third and final year of the pilot study. As in 1989, PIT tagging in 1990 was concentrated in the Middle Fork of the Salmon River drainage; a primary production area for wild spring chinook salmon in Idaho. Here we report the

results of the third year of the pilot study and summarize the outmigration timing results for all 3 years.

Methods

Wild Fish

During August and September 1990, we collected and PIT tagged wild spring/summer chinook salmon parr in nine streams in Idaho and three streams in Oregon (Fig. 1). Specific streams for tagging wild spring chinook salmon parr were chosen in the following areas: Bear Valley Creek, Elk Creek, Cape Horn Creek, Marsh Creek, Big Creek in the Middle Fork of the Salmon River drainage; Valley Creek and East Fork of the Salmon River in the upper Salmon River drainage; and Catherine Creek and the Lostine River in Oregon. Wild summer chinook salmon parr were tagged in the Secesh and South Fork of the Salmon Rivers in Idaho, and the Imnaha River in Oregon.

Fish were collected and tagged from various reaches of each stream. Collecting and PIT tagging procedures described by Matthews et al. (1990) remained the same for our field work in 1990.

Over the course of the 3-year study, wild parr were PIT-tagged in many streams in Idaho and Oregon (Table 9). We developed a systematic comparison of the overall outmigration timing differences among the 3 years at Lower Granite Dam by combining the recoveries of individual streams for each year.

Hatchery Fish

PIT-tagged spring chinook salmon from Dworshak and Sawtooth Hatcheries and summer chinook salmon from McCall Hatchery were compared to wild fish. Dworshak and Sawtooth Hatchery fish were

tagged by NMFS personnel for a pilot study by the U.S. Fish and Wildlife Service (USFW) to examine the relationship between bacterial kidney disease (BKD) and smolt transportation. The USFWS will report procedures and recovery percentages at dams for their study fish in a separate document. McCall Hatchery fish were PIT tagged by the Idaho Department of Fish and Game (IDFG).

Fish from several different hatcheries were PIT tagged over the course of this 3-year study (Table 9). We combined all hatchery recoveries for individual years to provide a comparison of the outmigration timing of hatchery fish among the 3 years of study.

Monitoring PIT Tags at Dams

During spring 1991, surviving spring/summer chinook salmon, PIT tagged for this study in summer 1990, migrated downstream volitionally through the hydroelectric complex on the Snake and Columbia Rivers. Of the eight dams the smolts pass, three are equipped with complete smolt collection and PIT-tag monitoring systems. These are Lower Granite and Little Goose Dams on the Snake River and McNary Dam on the Columbia River (Fig. 1). These dams also serve as the collection points for the smolt transportation program.

At these facilities, all collected smolts that pass through the outlet orifices of the fish and debris separators and through the distribution flumes were electronically interrogated for PIT tags. Dates and times of passage were electronically recorded rounded to the nearest second and stored by computer. All recovery data were transferred once each day to the mainframe computer operated by the Pacific States Marine Fisheries Commission in Portland, Oregon.

Results

Collection and Tagging

During 25 working days in August and September, we collected 8,628 wild spring/summer chinook salmon parr in Idaho and Oregon (Table 10 and Appendix Table 17). Of these, 8,250 were PIT tagged and released back into the streams. The numbers tagged and released per stream ranged from 164 in Cape Horn Creek to 1,023 in Valley Creek.

The fork length of PIT-tagged wild fish from Idaho streams ranged from 49 to 104 mm with an overall average of 68 mm (Table 10). The weight ranged from 1.0 to 14.2 g with an overall average of 4.2 g. In the three Oregon streams, the fish were larger, with an average fork length of 77 mm (range 56-104 mm). The average weight of 4.2 g (range 1.6-11.1 g) may not accurately reflect the true average weight of tagged fish in Oregon since only 6.9% of tagged fish were weighed.

As during previous years, mortality and tag loss were low in 1990 (Table 11 and Appendix Table 18). Due to low densities of chinook salmon parr in Idaho streams, collections were made by electro-fishing in all streams in that State. In Oregon streams, the fish were collected either by seines or a box trap. Collection mortality was 1.5 and 0.3% for Idaho and Oregon streams, respectively. The tagging mortality was 0.2% for Idaho and 0.6% for Oregon streams. Of the 1,706 fish held for 24-hour delayed mortality and tag loss in Idaho and Oregon, we recorded 0.4% mortality and 0.0% tag loss. The overall observed mortality was 1.6% for the two states combined.

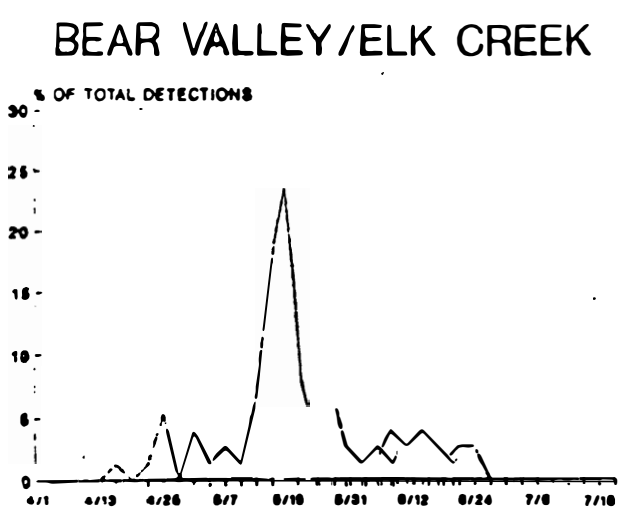
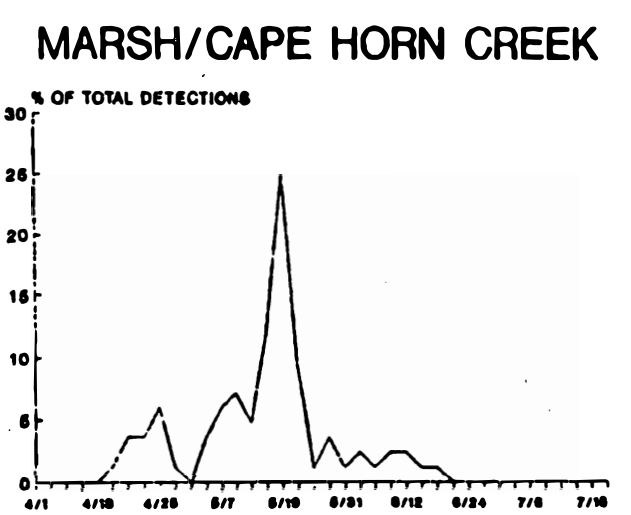
diverted, scanned, weighed, and measured. From the time of tagging, in late summer 1990, to recovery, the average gain in length was 38.5 mm (range 22 to 84 mm), and the average gain in weight was 10.2 g (range 4.1 to 36.3 g). Average time between measurements was 267.9 days (range 218 to 338 days).

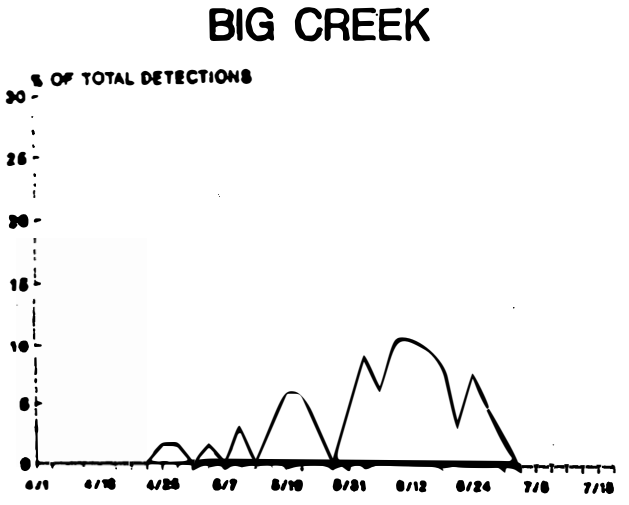
Outmigration Timing at Lower Granite Dam

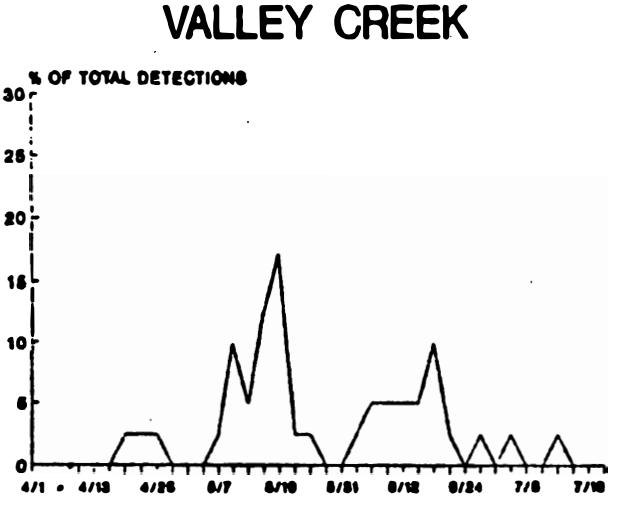
Timing of outmigrations for individual and combined streams along with hatchery populations were calculated from 1 April to 20 July 1991 by the methods used in 1989 and 1990 (Matthews et al. 1990, 1992).

Spring chinook salmon--Figure 3 presents the timing of outmigrations passing Lower Granite Dam of spring chinook salmon smolts for individual streams and hatcheries in 1991. As during the previous 2 years, wild fish outmigration timing varied among individual streams. In the upper Middle Fork of the Salmon River drainage, fish from the Marsh/Cape Horn Creek and the Bear Valley/Elk Creek areas peaked around 20 May with the 50th percentiles of marked fish passing the dam about the same day. The 90th percentile passed on 3 June for the Marsh/Cape Horn Creek area and on 14 June for the Bear Valley/Elk Creek area. This outmigration timing was later than in 1990, when the 50th percentile passed on 29 April for Marsh Creek and on 2 May for Bear Valley Creek, and the 90th percentile passed on 31 May for both streams (Matthews et al 1992). Fish from Big Creek, a tributary of the lower Middle Fork of the Salmon River, peaked at the dam on 14 June, much later than other stocks. The 50th and 90th percentiles passed on 10 and 26 June, respectively. This stream also displayed the









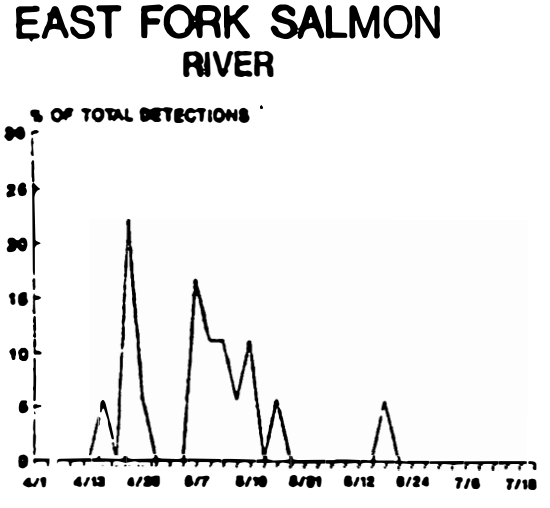


Figure 3.--The outmigration timing of spring chinook salmon smolts at Lower Granite Dam in 1991 by individual streams and hatcheries.

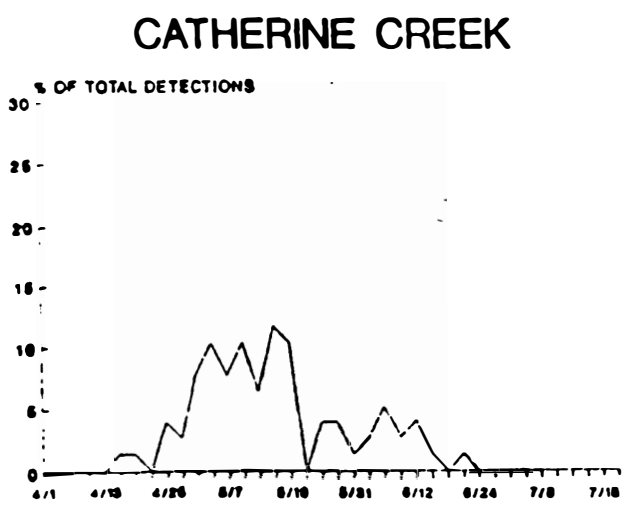

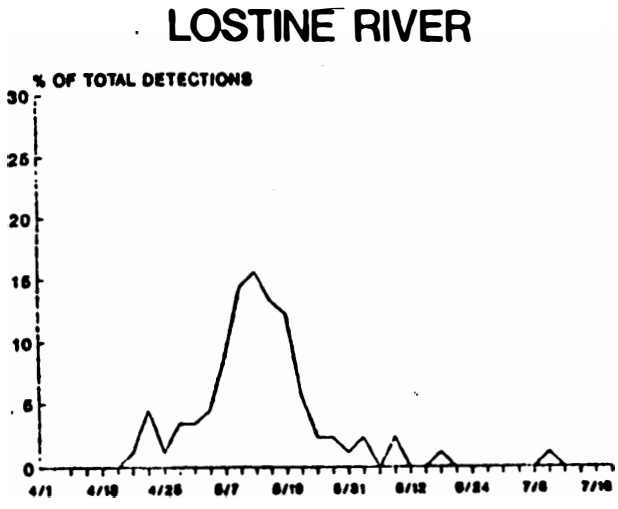

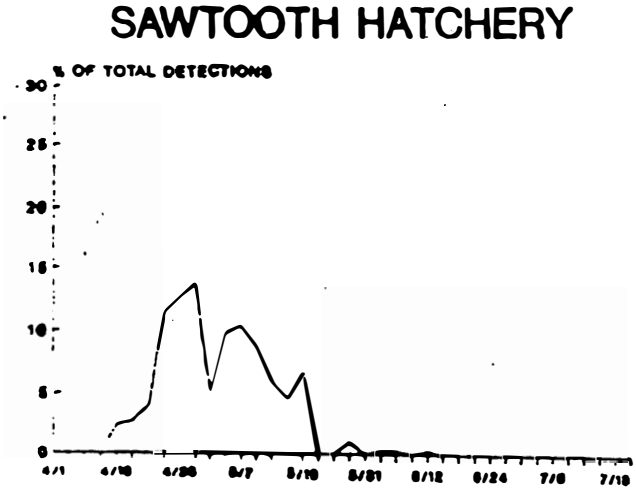

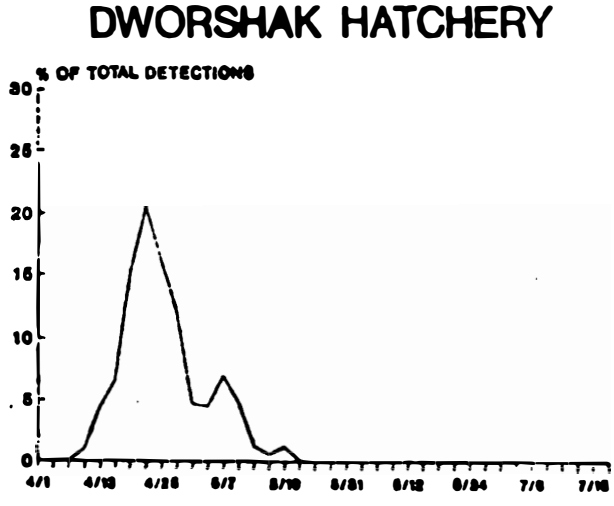

Figure 3.--Continued.

latest timing during 1990. Moreover, compared to 1990, the 1991 outmigration timing for this stream was 11 days later for the 50th percentile and 4 days later for the 90th percentile passage. Outmigration timing for wild spring chinook salmon from Valley Creek, a tributary of the upper Salmon River, was similar to timing observed for streams in the upper Middle Fork of the Salmon River. Migration peaked at the dam on 20 May, with the 50th and 90th percentiles passing on 20 May and 20 June, respectively. This was the latest timing for this stream during the 3-year study. Fish from the East Fork of the Salmon River, another tributary of the upper Salmon River, showed a much different outmigration timing at the dam than fish from Valley Creek and the streams in the Middle Fork of the Salmon River. Migration for these fish peaked at the dam twice, once on 23 April and again on 11 May, with the 50th and 90th percentiles passing on 9 and 26 May, respectively. The outmigration timing for this stream in 1991 was similar to 1989 when the 50th and 90th percentiles passed the dam on 3 and 18 May, respectively (Matthews et al. 1990). The timing of the outmigrations of wild spring chinook salmon smolts from the Lostine River and Catherine Creek, tributaries of the Grande Ronde River in Oregon, was similar. Migration peaked at the dam about 12 May (Catherine Creek displayed a second peak on 20 May), with the 50th percentile passing the dam on 14 May. The 90th percentile passage dates were 26 May for the Lostine River and 8 June for Catherine Creek.

The outmigration period of hatchery spring chinook salmon smolts at Lower Granite Dam was much more compressed than for their

wild counterparts. Hatchery fish were in abundance early in the outmigration, with very few detections at the dam after 15 May. Both Sawtooth and Dworshak Hatchery migrations peaked at the dam on 24 April. Sawtooth Hatchery fish displayed a more protracted outmigration period at the dam than Dworshak Hatchery fish. The 50th percentile passage occurred on 25 April for Dworshak and 3 May for Sawtooth Hatchery fish. The 90th percentile passages occurred on 9 and 17 May for the outmigrations for each hatchery, respectively. While Dworshak Hatchery fish displayed almost identical migration timing at the dam during both 1990 and 1991, Sawtooth Hatchery fish showed a later migration for 1991 than for either 1989 or 1990 (Matthews et al 1990, 1992).

To illustrate the overall difference in timing between wild and hatchery fish in 1991, we combined all wild and hatchery recoveries into their respective groups (Fig. 4). The combined wild fish outmigration at Lower Granite Dam was characterized by a large peak on 20 May, coincidental with the highest flow and turbidity of the year. The 50th percentile passed the dam on 19 May and the 90th percentile passed the dam on 15 June. The combined hatchery outmigration peaked on 24 April, with the 50th and 90th percentiles passing the dam on 26 April and 10 May, respectively.

In general, the five peak passage periods for wild spring chinook salmon smolts at Lower Granite Dam during the past 3 years (Fig 5), coincided with periods of peak river discharge at the dam. However, the peaks tended to consist primarily of fish from a few streams each year. Whether the increased river discharge moved these groups of fish through the reservoir or were simply

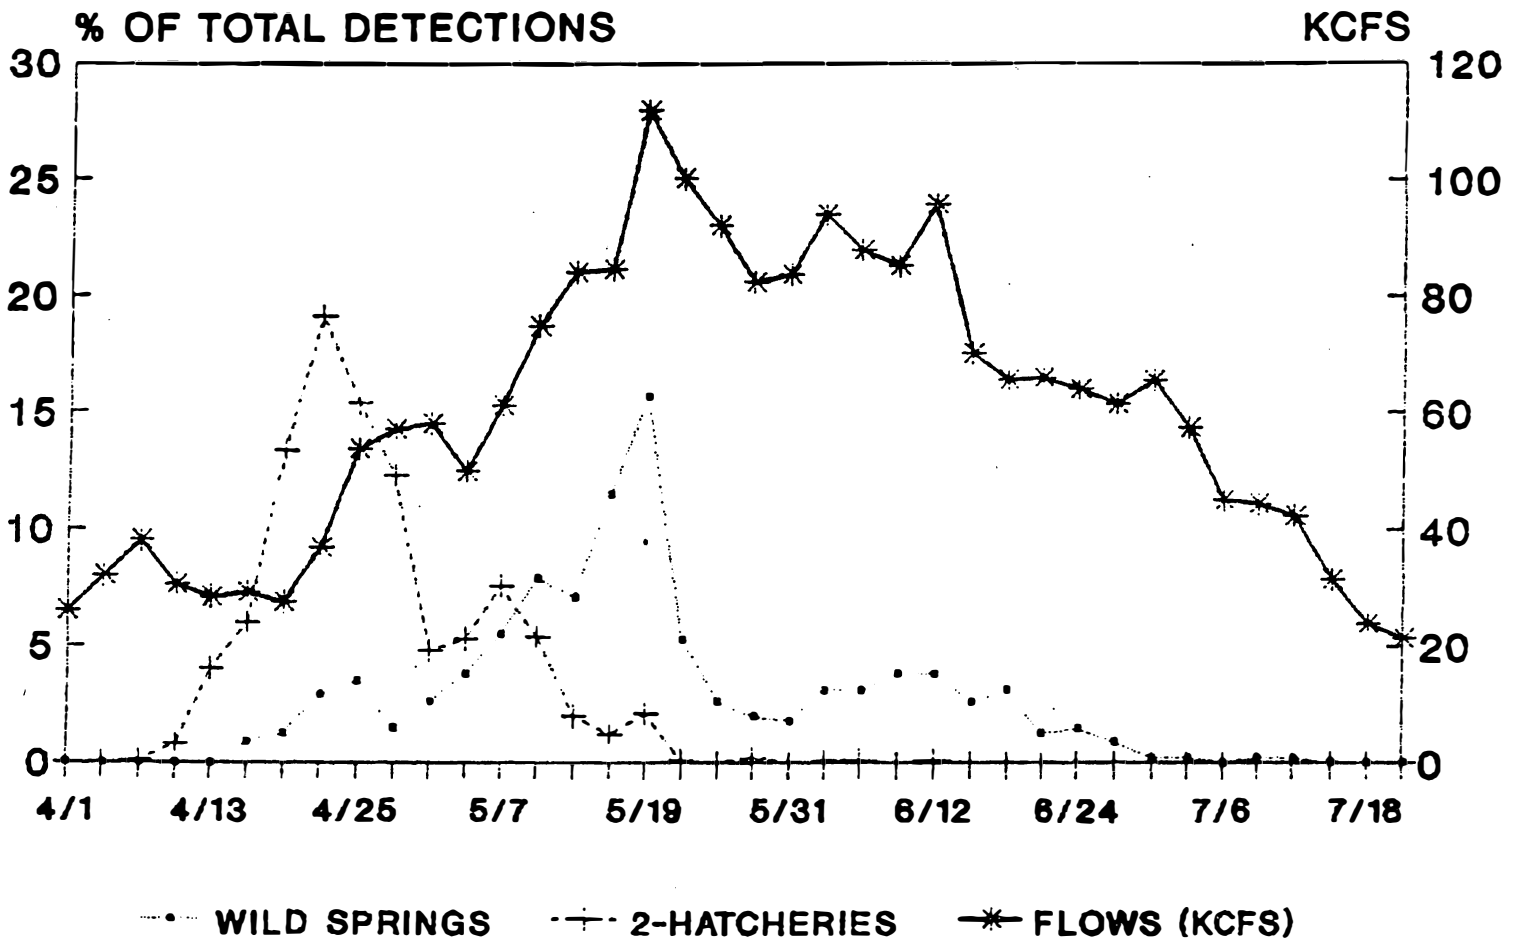

Figure 4.--The outmigration timing of wild and hatchery-reared spring chinook salmon at Lower Granite Dam in 1991. Data represents recoveries from all wild streams combined and Dworshak and Sawtooth Hatcheries combined.

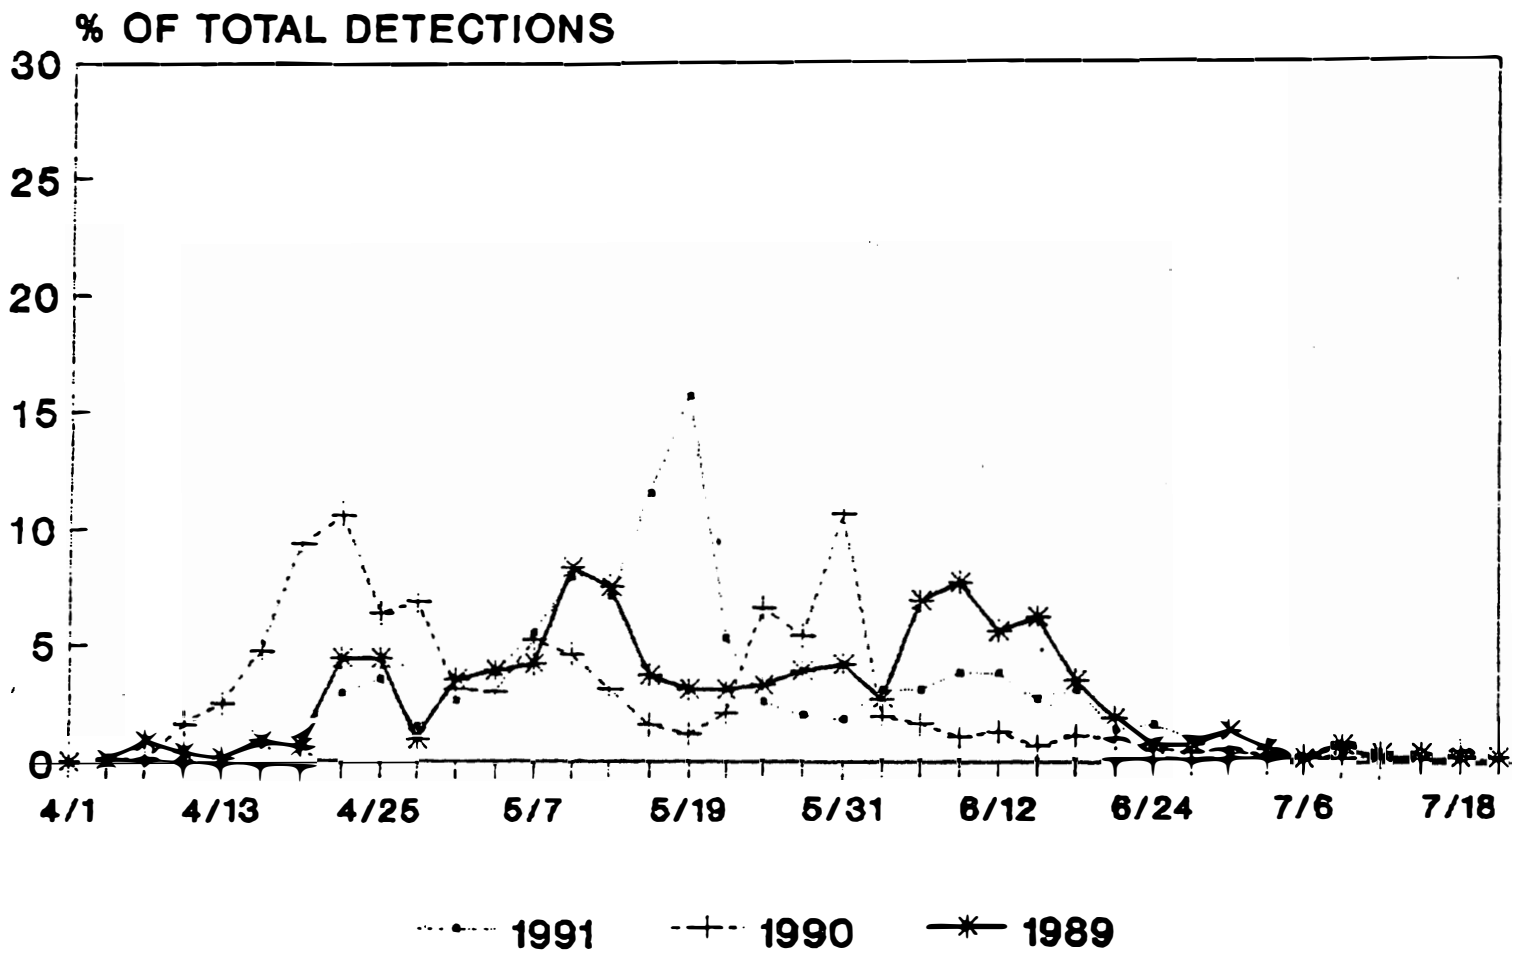

Figure 5.--The outmigration timing of wild spring chinook salmon at Lower Granite Dam in 1989, 1990, and 1991. Data represents recoveries from all wild streams combined each year.

coincidental with their arrival at the dam was unknown. Since the peaks occurred almost simultaneously with increased discharge, it seems likely that the fish were in the immediate vicinity of the dam and were simply moved through it rapidly by the increased flow. Although in 1991 the peak outmigration periods occurred at different times than in 1989 (the 1989 study did not include fish from the Middle Fork of the Salmon River), the 50th and 90th percentile passage dates at the dam were almost identical for both years. In contrast, the 50th and 90th percentile passage dates were about 12 and 10 days earlier in 1990 than in 1989 or 1991.

In contrast to wild fish, the outmigration timing for hatchery spring chinook salmon was remarkably similar for all 3 years of the study (Fig. 6). Migrations of hatchery spring chinook salmon smolts peaked at the dam during the same 3-day period (22-24 April) under highly variable flows, averaging 111, 73, and 37 kcfs during the 3-day periods in 1989, 1990, and 1991, respectively. The 50th and 90th percentile passage dates were also similar, varying by only 4 to 6 days over the 3 years.

Summer chinook salmon--Figure 7 illustrates the outmigration timing of wild and hatchery summer chinook salmon smolts at Lower Granite Dam in 1991. Migration of Secesh River fish peaked at the dam on 24 April, with the 50th and 90th percentiles passing on 27 April and 14 June, respectively. This stream exhibited similar outmigration timing patterns in all 3 years, with 50% of the fish passing the dam by the last week of April and 90% passing by the second week of June. Migration of fish from the South Fork of the Salmon River peaked on 20 April and 22 May; the 50th and 90th

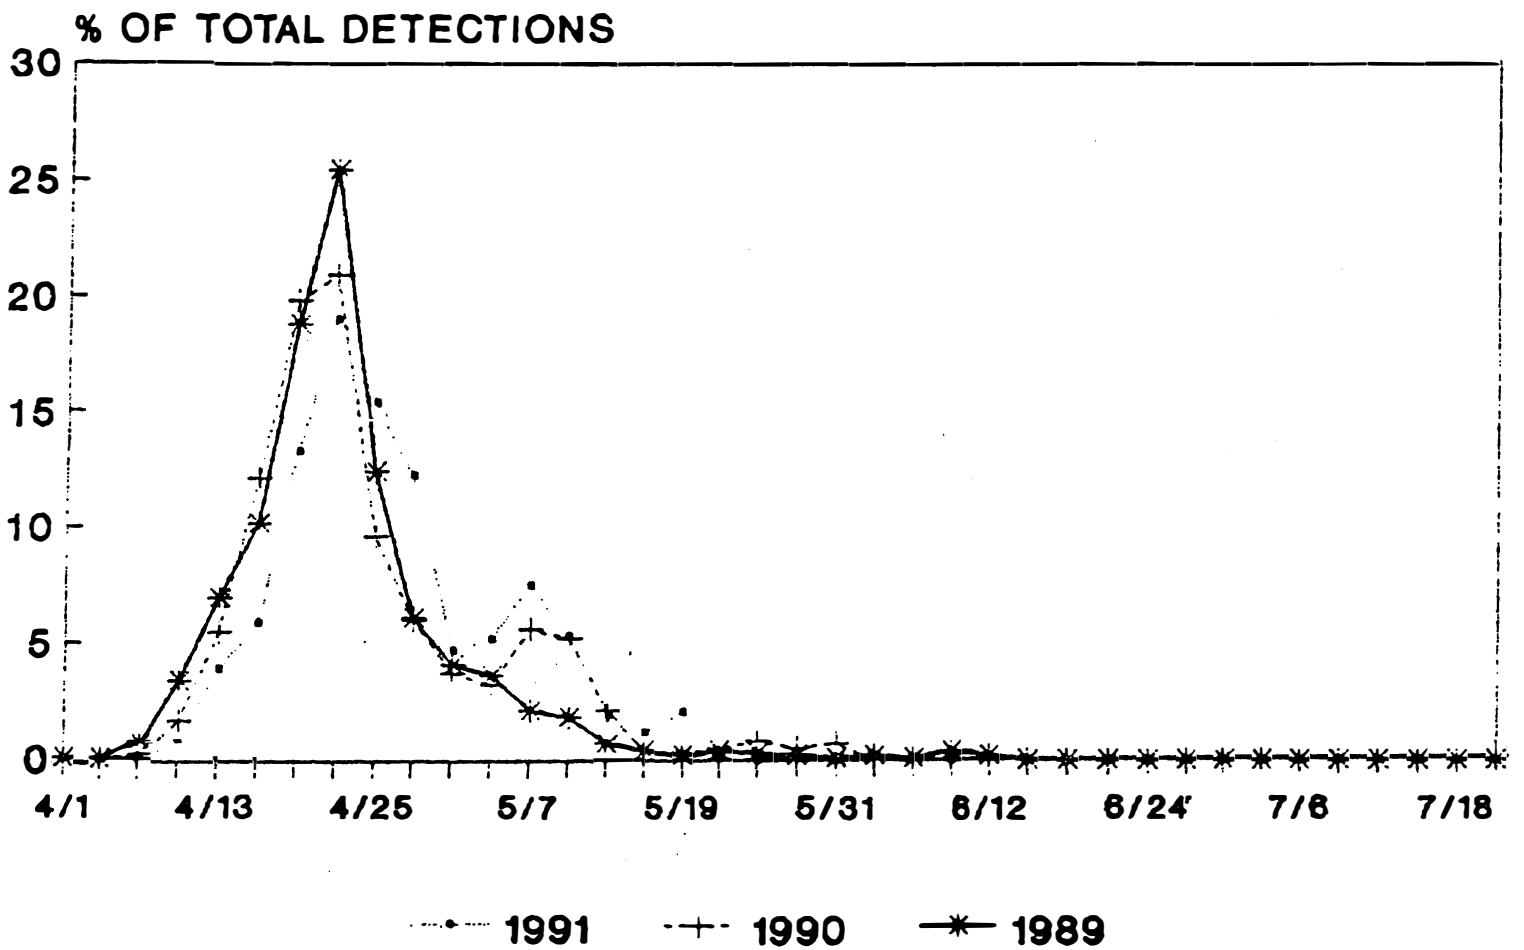

Figure 6.--The outmigration timing of hatchery-reared spring chinook salmon at Lower Granite Dam in 1989, 1990, and 1991. Data represents recoveries from Sawtooth and Lookingglass Hatcheries combined in 1989, and from Sawtooth and Dworshak Hatcheries combined in 1990 and 1991.

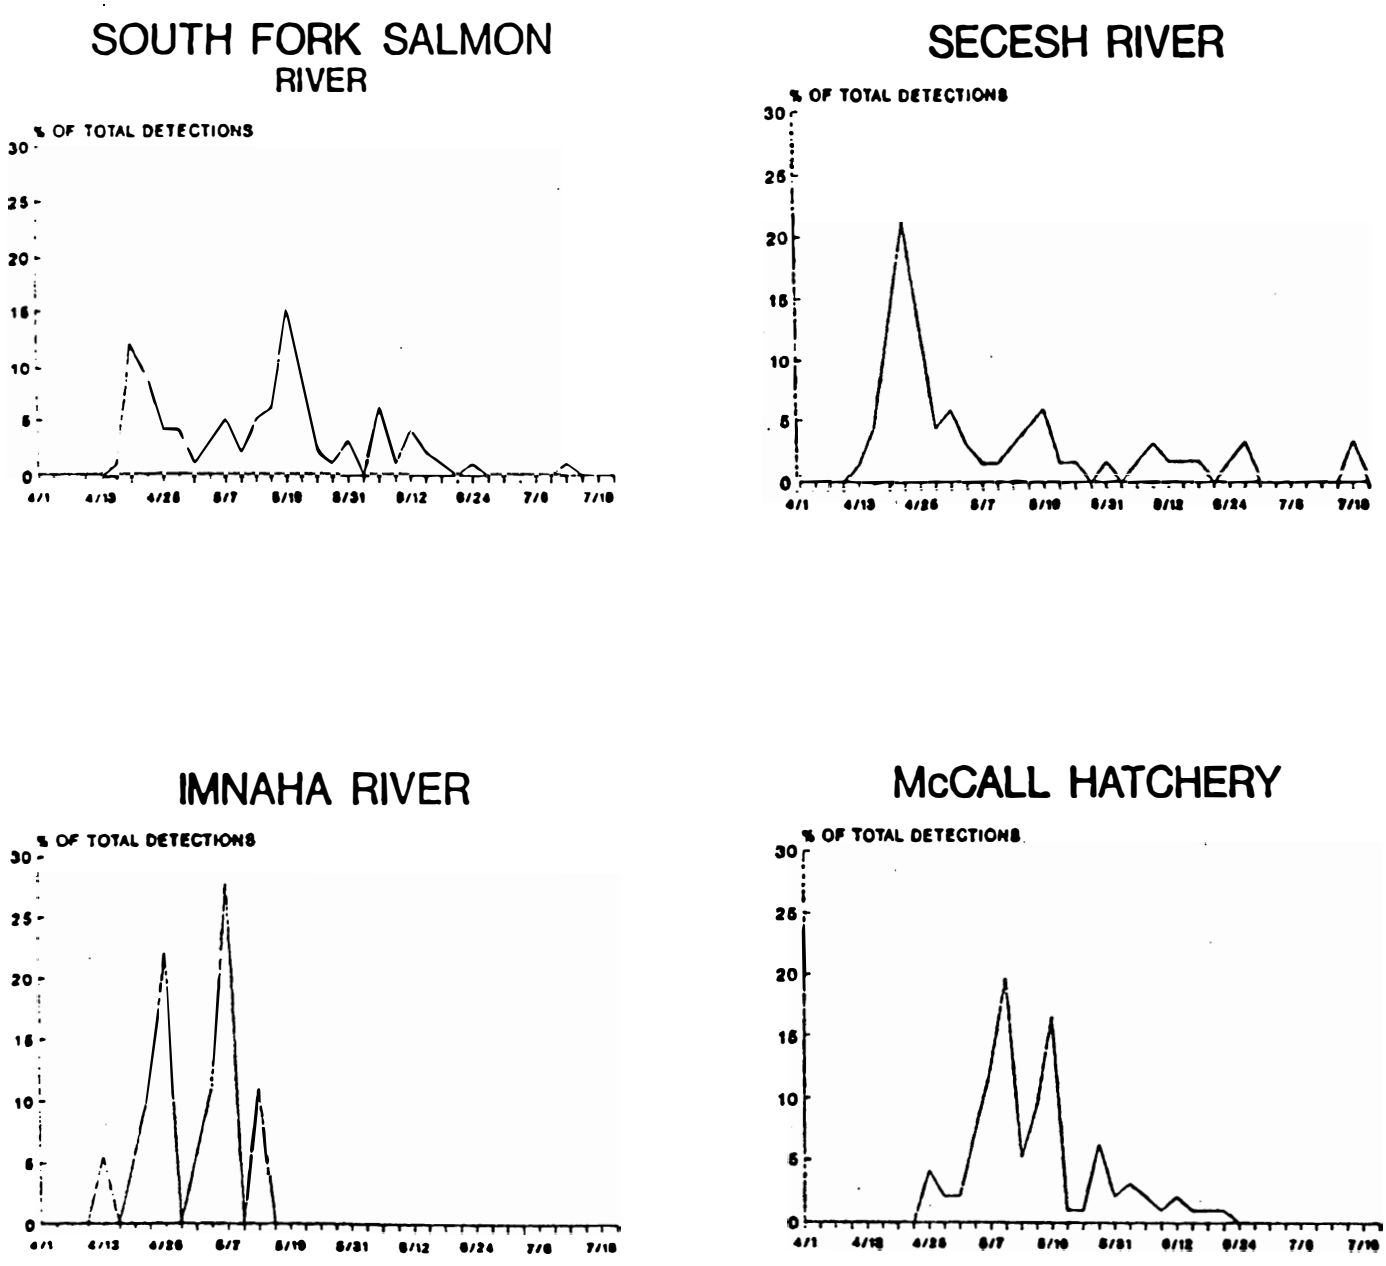

Figure 7.--The outmigration timing of summer chinook salmon at Lower Granite Dam in 1991 by individual streams and McCall Hatchery.

percentiles passed the dam on 16 May and 10 June, respectively. This pattern was a similar to the outmigration timing observed at the dam in 1989 (the only other year of tagging in this stream), with 50% passing by the middle of May and 90% passing by the second week of June in both years (Matthews et al 1990). Migration of fish originating in the Imnaha River peaked at the dam on 25 April and 8 May, with the 50th and 90th percentiles passing the dam on 1 and 13 May, respectively. In this stream, the earliest timing of all wild fish during all 3 years of study was observed, with over 50% of the fish passing the dam in April and over 90% passing by mid-May.

In 1991, the outmigration period for hatchery summer chinook salmon smolts at Lower Granite Dam was later and more compressed than for their wild counterparts, but not as compressed as the outmigration of hatchery spring chinook salmon smolts. Migration peaks of hatchery summer chinook salmon occurred on 12 and 19 May, with the 50th and 90th percentiles passing the dam on 14 May and 4 June, respectively. The 50th and 90th percentile passage dates for these fish in 1991 were very close to those for 1989 (Matthews et al. 1990).

The combined outmigration timing of all wild summer chinook salmon showed peaks occurred on 20 and 24 April and on 20 May, with the 50th percentile passing the dam on 8 May and the 90th percentile on 11 June (Fig. 8).

During the 3-year study, peak outmigration periods at Lower Granite Dam for wild summer chinook salmon (Fig. 9) were generally variable and did not necessarily coincide with peaks in river discharge. In all 3 years, peak outmigration periods occurred in

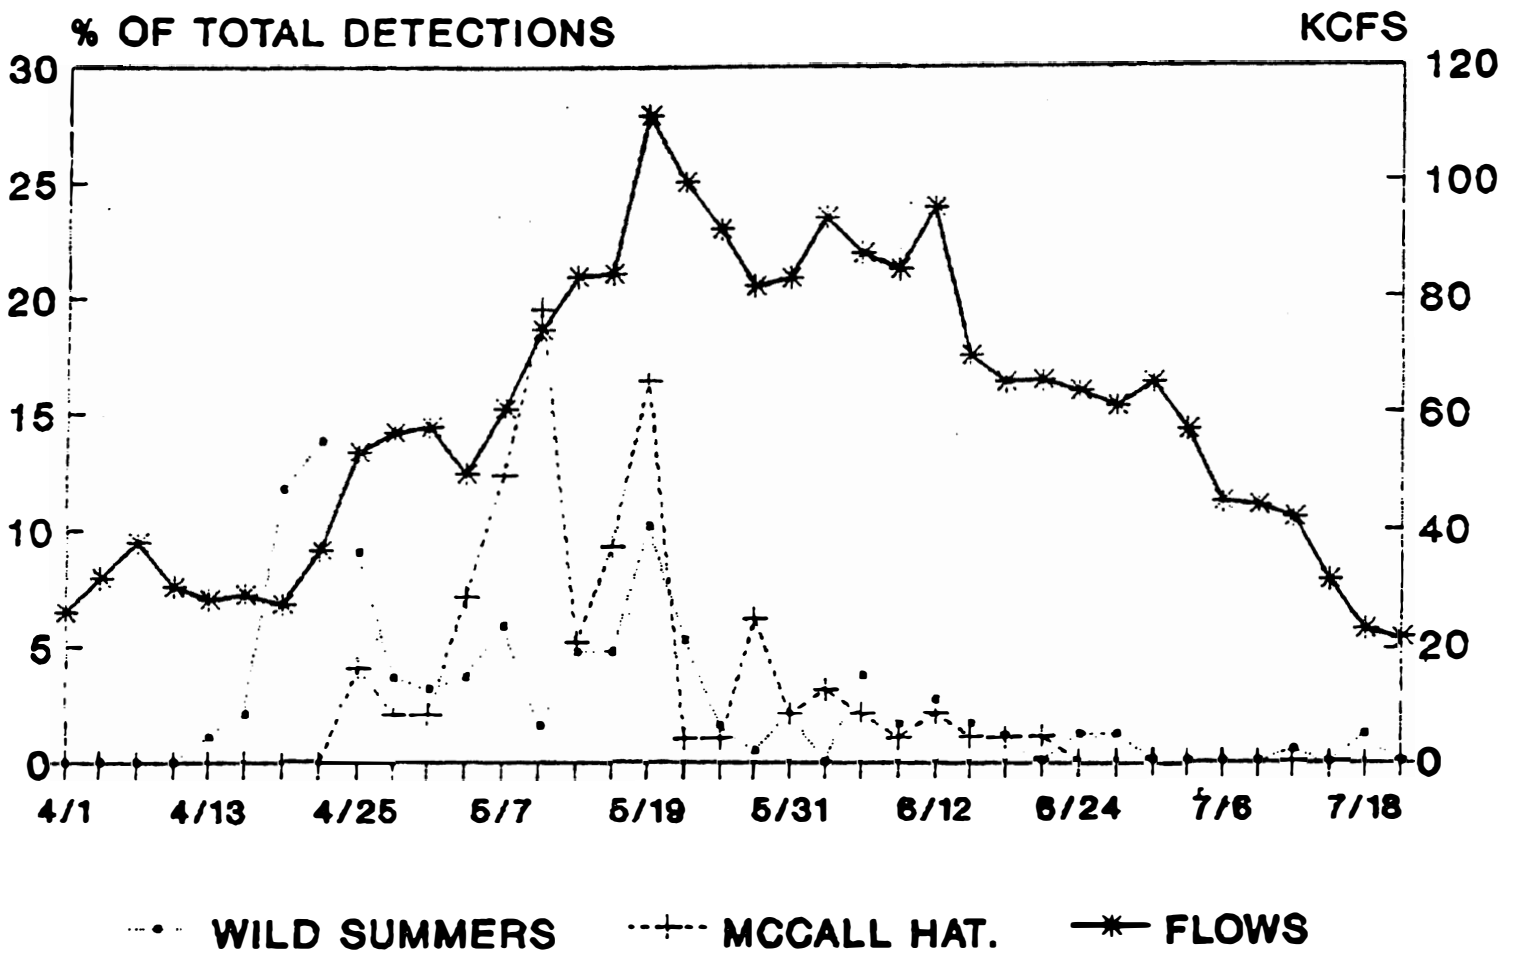

Figure 8.--The outmigration timing of summer chinook salmon at Lower Granite Dam in 1991. Data represents recoveries from both wild streams combined and McCall Hatchery.

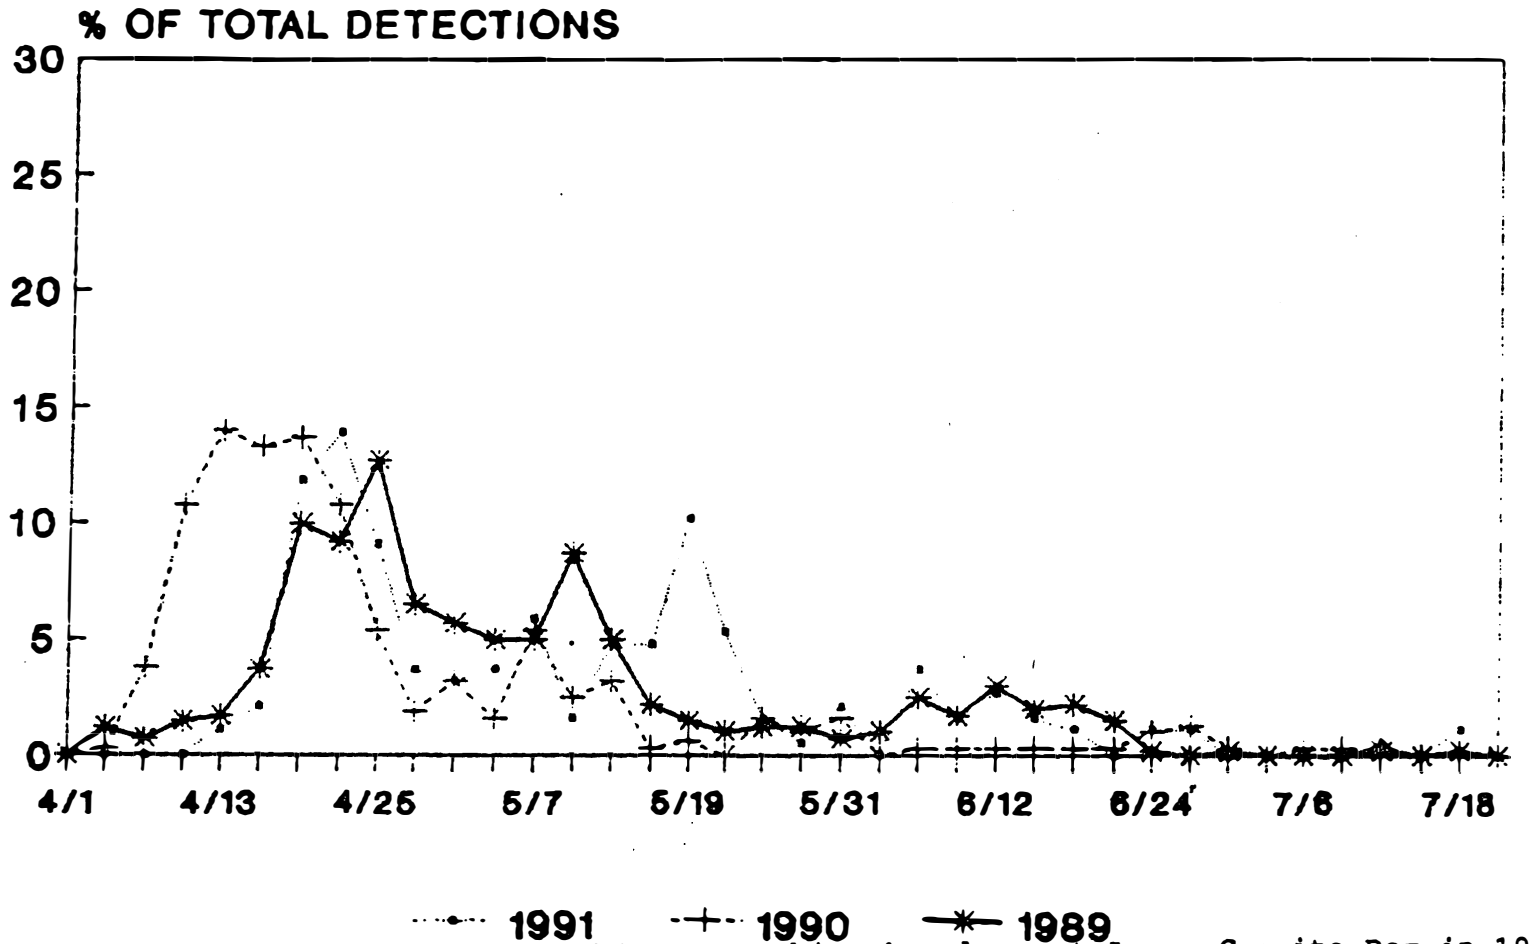

Figure 9.--The outmigration timing of wild summer chinook salmon at Lower Granite Dam in 1989, 1990, and 1991. Data represents recoveries from both wild streams combined for each year.

April under moderate to low river flows of 86.9, 48.9, and 36.9 kcfs for 1989, 1990, and 1991, respectively.

During both years that hatchery summer chinook salmon were included in the study (1989 and 1991), they displayed later timing than their wild counterparts (Fig. 10). Also, in contrast to wild smolts, peak passage periods for hatchery fish were similar in both years.

Discussion

Collection and tagging methods used in the summers of 1988 and 1989 were again highly effective and successful during summer 1990. However, due to the low densities of chinook salmon parr in most streams during 1990, we covered roughly twice the area in the streams to collect half as many fish as were collected in 1989. Because of the low parr densities, we had to use electro-fishing in most streams, and collection mortality was slightly higher than in 1988 or 1989. However, the tagging and 24-hour delayed mortalities were lower than during the previous 2 years. With the present equipment, an additional crew, and adequate parr densities, we believe it would be possible to capture and tag up to 80,000 wild fish during August and September for a full-scale transportation study. However, due to severely reduced escapements of wild adult spring and summer chinook salmon into Idaho and Oregon streams in recent years, a full-scale study will not be feasible in the near future.

Although recovery rates of wild fish at collector dams were higher during spring 1991 than the previous two springs, they were

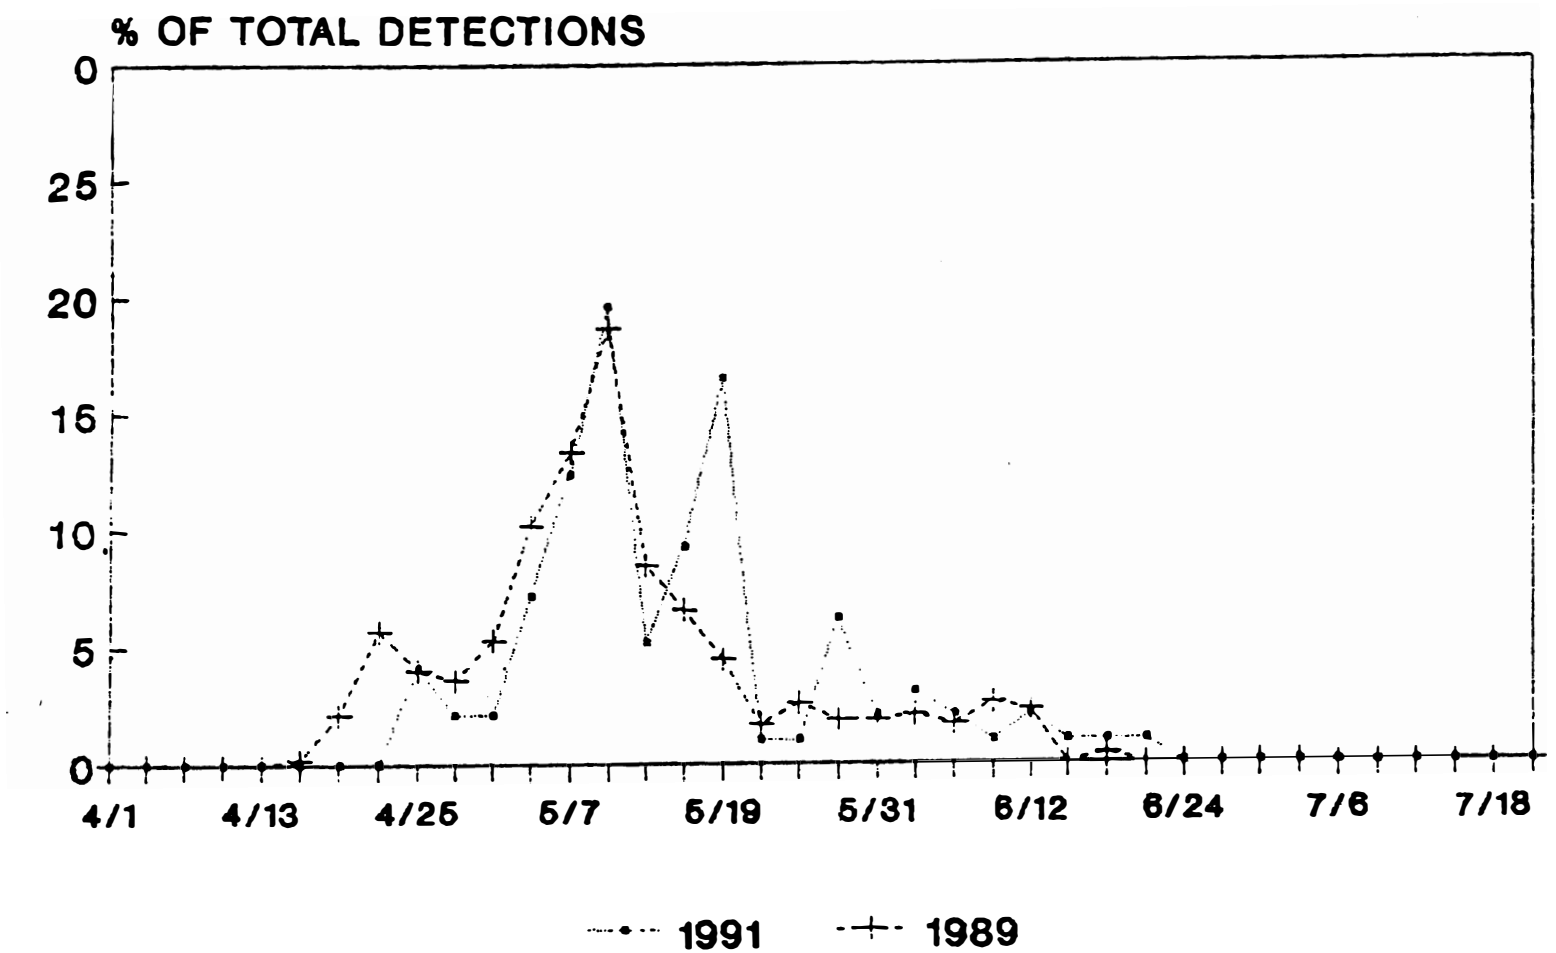

Figure 10.--The outmigration timing of hatchery-reared summer chinook salmon at Lower Granite Dam in 1989 and 1991. Data represents recoveries from McCall Hatchery for each year.

still lower overall than originally anticipated. However, recoveries from some streams approached original expected recovery rates at the dams. We appear to have overestimated overwinter survival for most years. However, all 3 study years coincided with the extended drought period in the Snake River. Matthews et al. (1990) reported that environmental conditions were severe during the winter of 1988-89, which may have reduced overwinter survival more during the first year of the study. During the second study year, the winter was not as severe; even so, we only realized a 31% increase in recovery of wild fish at Lower Granite Dam. In streams tagged in both 1988 and 1989, two had lower and two had higher recovery rates at the dam during the second year. This may suggest that fish originating from streams in the Middle Fork of the Salmon River, which were added during the second study year, may have higher overwinter survival regardless of environmental conditions. The winter for the third study year of 1990-91 was relatively mild. Substantial increases in recovery rates of wild fish were observed at Lower Granite Dam from all streams in the Middle Fork of the Salmon River except Marsh Creek. In the remaining four streams, two had higher and two had lower recovery rates at the dam than during the previous year.

The recovery proportions measured for wild fish among the three collector dams were similar for all 3 years of study. This was in spite of the fact that environmental conditions (particularly temperature and flow) varied considerably over the 3 years.

The outmigration timing of wild spring and summer chinook salmon smolts from individual streams at Lower Granite Dam varied in

1991, and also differed from individual streams in the 1989 and 1990 outmigrations. The outmigration timing of fish from individual wild spring chinook salmon streams also varied more than that of fish from individual wild summer chinook salmon streams during the 3 years of study. In all 3 years, wild spring chinook salmon smolt outmigrations were protracted and encompassed nearly the entire spring and early summer migration period. In the first 2 years, the combined outmigrations of these fish displayed two peaks; however, the first peak was earlier and stronger in 1990 than in 1989, resulting in an overall earlier passage observed at the dam. The third year differed from the previous two, with one strong peak passage period around 20 May. We suspect that different environmental conditions, extant during the late winters and early springs of the 3 years, resulted in the variability in outmigration timing among the years. In 1989, a late, cold winter and early spring produced lower water temperatures. Low temperatures probably delayed the outmigrations of wild fish, even though river flows were near average for the period in April. In 1990, the late winter and early spring period was very mild, producing warmer than normal spring water temperatures. This may have contributed to the earlier outmigration of wild fish for that year even though river flows were below normal for the period. In 1991, the spring and early summer were the coldest in many years, and the resultant low water temperatures may have contributed to the late outmigrations of these fish. River flows were also lower than normal for this period. Raymond (1979) cites water temperature as one of the most important

factors involved in triggering the downstream movements of hatchery and wild chinook salmon smolts in spring.

Hatchery spring chinook salmon smolts were less influenced by differing environmental factors. In all 3 years, these fish displayed virtually the same outmigration pattern, with migration peaking at the dam within the same 3-day period.

In all 3 years of study, wild summer chinook salmon smolt migrations peaked at Lower Granite Dam in April, before wild spring chinook and hatchery summer chinook salmon smolts. Moreover, these fish passed the dam earlier in 1990 than in 1989, even under lower river discharge in 1990.

Outmigration timing of hatchery spring and summer chinook salmon smolts and wild summer chinook salmon smolts may be more closely related to the time of year than to river discharge at the dam. In contrast, the peak outmigration periods for wild spring chinook salmon coincided with peak flow periods at the dam. In addition to flow, other factors such as physiological development, variability in stock behavior, and other environmental factors may affect the passage timing of wild chinook salmon smolts.

Data from this pilot study have provided valuable insight concerning the migrational behavior of different stocks of wild chinook salmon smolts in the Snake River Basin. These studies should continue in order to characterize run-timing of various stocks of wild fish. Data should be collected over several years, encompassing different environmental conditions. Information gained will be critical for making sound management decisions to provide for increased survival of all stocks in the future.

ASSESSMENT OF A PIT-TAG DETECTION/DIVERSION SYSTEM AT LOWER GRANITE DAM

Introduction

In spring 1989, a PIT-tag detection/diversion system was installed and tested in the juvenile fish collection facility at Lower Granite Dam (Matthews et al. 1990). The principal feature of the system is a sliding gate (slide gate) in the bottom of each of two flumes exiting the fish and debris separator. The slide gates divert or remove PIT-tagged fish from the general population of fish passing through the flumes to the collection raceways or barges. During the first year of testing (1989), several major design problems were identified and corrected, and more testing was conducted during the 1990 smolt outmigration (Matthews et al. 1991).

The 1990 tests indicated that the corrections and adjustments produced the desired results. For example, by increasing the slope of the flumes and stabilizing the velocity of the water exiting the separator, the overall average number of untagged fish diverted per diversion cycle decreased from 1.7 in 1989 to 1.2 in 1990. Also, mortality rates for spring/summer chinook decreased from 0.4% in 1989 to 0.1% in 1990, and for steelhead from 8.8% in 1989 to 0.6% in 1990. However, when hourly facility counts exceeded 20,000 fish or when steelhead numbers were high, we observed higher than expected rates of untagged fish diverted per cycle, injuries, and mortalities (Matthews et al. 1991).

After the 1990 testing season, two major changes were recommended and incorporated into the system. First, both of the flumes exiting the fish and debris separator were painted black on

all interior surfaces. Lids, with their undersides painted black, were fabricated to cover the tops of the flumes. These modifications were intended to eliminate any light stimulus that might influence fish behavior. It was postulated that some of the fish, particularly steelhead, were reacting to the brightly lit flume by swimming vigorously against the current. This would cause the fish either to delay their movement between the PIT-tag detector and the slide gate or to delay their departure from near the slide gate. In the first case, a PIT-tagged fish might not be diverted as desired, while in the second case, the chances of diverting untagged fish might increase whenever a PIT-tagged fish activated the slide gate. It was believed that darkening the flumes would alleviate these problems by decreasing the volitional swimming of steelhead smolts as they left the separator.

The second adjustment was the addition of a buffer near the end of the slide-gate closure. In the past, the ram controlling the slide gate closed the gate at a uniform speed until the gate was completely closed. Because of this, fish caught in the gate as it closed had an increased chance of injury or death. The buffer allowed the slide gate to close at full speed until it was 2.5-5.0 cm from complete closure. At this point, the slide gate slowed down significantly in order to allow any fish in the area of the leading edge of the slide gate time to escape before complete closure.

The primary objectives of the 1991 testing were to determine if these changes produced the desired effects of decreasing injuries, mortalities, and numbers of untagged fish diverted per cycle. These

effects were particularly critical during periods when facility fish counts were greater than 20,000 fish per hour.

Methods

As in past years, the efficiency of the system was defined as the ratio of untagged fish diverted per PIT-tag diversion cycle. Since this ratio is a function of cycle time and number of fish moving past the system per hour, an expected value for this ratio can be estimated. During the 1990 testing season, twice as many PIT-tagged fish passed through the south than the north flume (Matthews et al. 1992). This pattern was observed again during the 1991 testing season. Assuming that PIT-tagged fish were randomly interspersed among other fish, PIT-tag detections indicated that 33% of the fish passed through the north flume and 67% passed through the south flume. Because of this inequity, an expected value for the number of untagged fish per cycle was designed to reflect the non-equal distribution of fish between the two flumes. The formula used to estimate the expected value was:

$$\text{Expected Value} = \sum_{i=1}^{n}\left[\frac{H_i\left(P^2 t_{ni} + (1-P)^2 t_{si}\right)}{3600n}\right]$$

where: n = the number of tests in each grouping

i = 1,...,n

H_i = the expanded hourly facility count for test i

P = 1/3 (the amount of fish passing through the north flume)

t_{ni} = the cycle time for the north slide gate for test i

t_{si} = the cycle time for the south slide gate for test i

This formula assumed a linear relationship between the facility count and the expected value. As the facility count increased, the expected value increased proportionally (Fig. 11).

The efficiency of the PIT-tag detection/diversion system was determined by conducting hourly tests during the 1991 smolt outmigration. Half of the tests were run at night, while the other half were split between early morning and mid-afternoon. The hourly count of fish passing through the facility and the number of PIT-tag diversion cycles were not known until after each hourly test was complete. The hourly fish counts were determined using the facility sample counts for each hour of testing.

At the end of each hourly test, fish were removed from the collection tank with a sanctuary dipnet and anesthetized. They were then scanned for PIT tags, identified by species, counted, and observed for injury and descaling. In addition, all PIT-tagged fish were weighed and measured to fork length. All fish were returned to the collection system for transportation after recovery from the anesthetic.

Results and Discussion

During the testing season, 150 successful tests were conducted (Table 12 and Appendix Tables 36 through 39). Several tests were aborted because of mechanical and/or electronic problems. Testing was planned to start in early April; however, due to low fish numbers, daily testing did not begin until late April. The highest hourly facility fish count tested was 39,300.

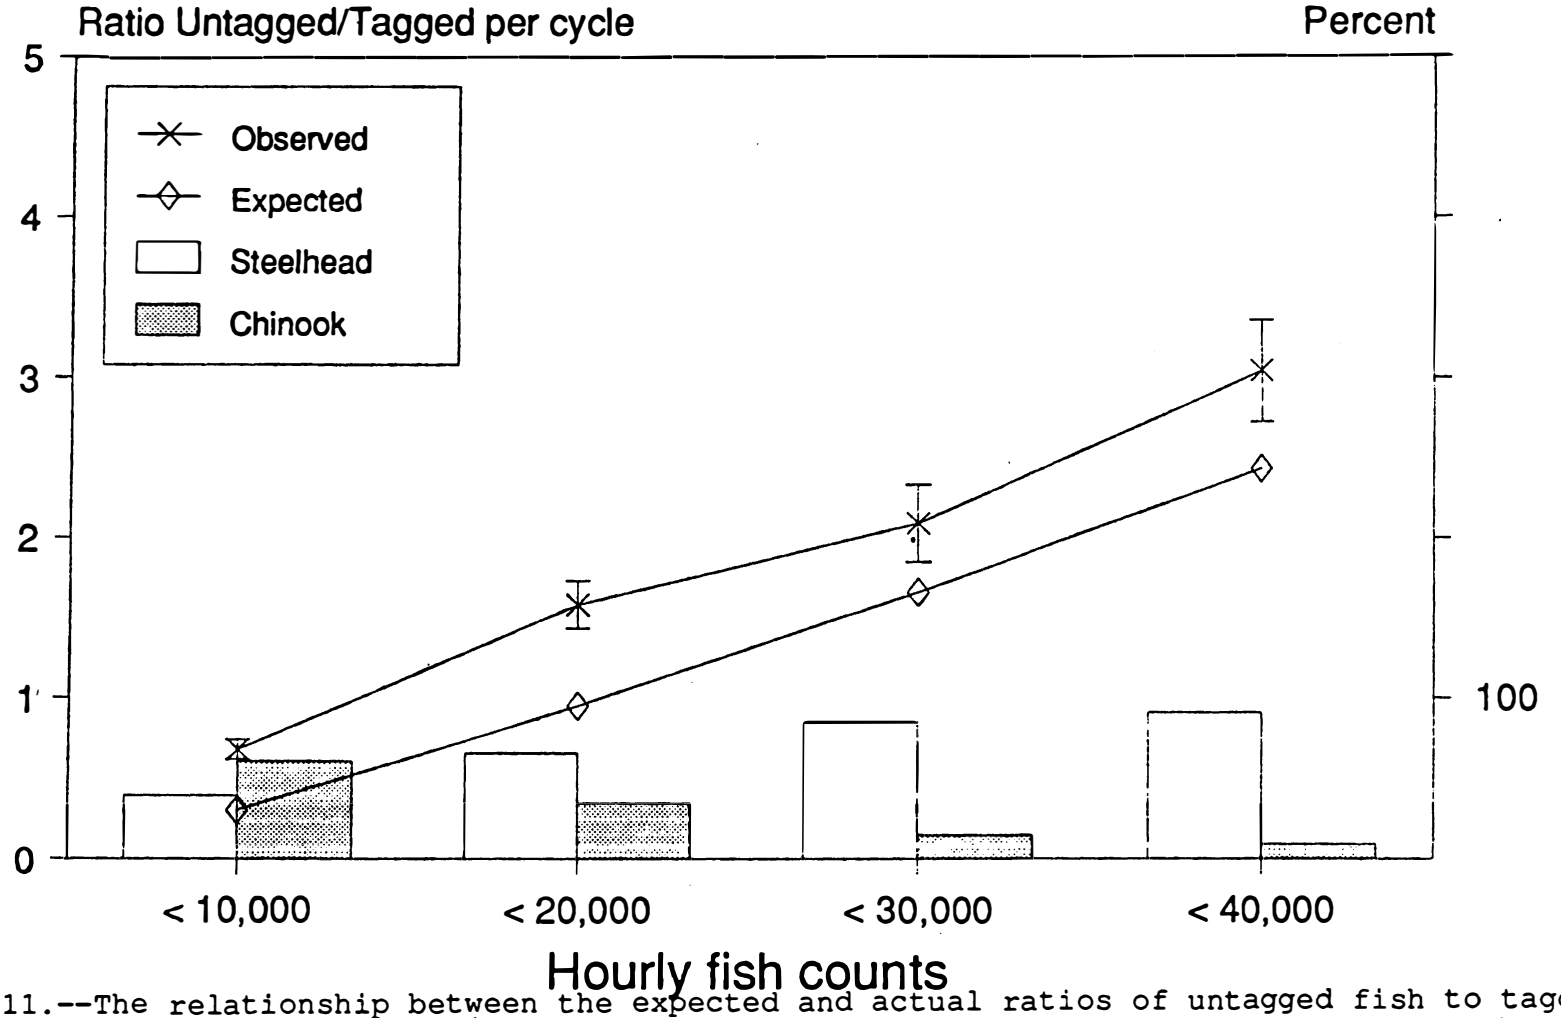

Figure 11.--The relationship between the expected and actual ratios of untagged fish to tagged fish diverted per diversion cycle when the percentage of steelhead was less than or greater than 50% of the sample.

Table 12.--Summary of results of PIT-tag detection/diversion system testing at Lower Granite Dam in 1991.

Hourly Fish Counts	Number of Tests	Untagged Fish per Cycle	Standard Error	Expected Value
< 5,000	60	0.43	0.07	0.18
5,001-10,000	43	0.97	0.09	0.49
10,001-15,000	24	1.39	0.16	0.82
15,001-20,000	12	1.97	0.29	1.22
20,001-25,000	4	1.92	0.31	1.54
25,001-30,000	2	2.43	0.34	1.89
30,001-35,000	3	3.19	0.54	2.34
35,001-40,000	2	2.83	0.25	2.56
Totals and Averages	150	1.03	0.07	0.58

The efficiency of the system ranged from 0.43 untagged fish diverted per cycle, when facility counts were below 5,000 fish per hour, to 3.19 untagged fish diverted per cycle when facility counts were between 30,000 and 35,000 fish per hour (Table 12).

In examining the effect of steelhead abundance on the efficiency of the system, the darkening of the flumes appeared to produce the desired result. The efficiency of the system was 0.62 untagged fish diverted per cycle when the percentage of steelhead was under 50%, and 1.32 untagged fish diverted per cycle when the percentage of steelhead was over 50% (Fig. 11). While this may seem like a large increase, it related to the hourly facility count. The average hourly facility count was 4,264 when steelhead comprised less than 50% of the population, but was 11,406 when steelhead comprised greater than 50% of the population. Since we defined the expected value as a linear function of the hourly facility count, the efficiency would have been expected to decrease more than it actually did based solely on the increase in the hourly facility count. Therefore, the numbers of steelhead in the population appeared to have no effect on the efficiency of the system.

The descaling/injury rates were somewhat greater than measured during the two previous seasons (Matthews et al. 1990, 1992), averaging 5.5% for spring/summer chinook and 3.2% for steelhead. These values were also somewhat higher than those measured for the collection facility in general (Ceballos et al. 1992). Presumably, the descaling/injury rates in our tests during all years were inflated to an unknown degree by collection and handling procedures during data retrieval.

The mortality rates in 1991 averaged 0.1% for spring/summer chinook salmon and 0.2% for steelhead. All of the mortalities were caused by the slide gate. These results represented no decrease for spring/summer chinook salmon from the previous year, but a 62% decrease for steelhead (Matthews et al. 1992). The substantial decrease in mortality for steelhead indicated that the addition of the buffer prior to complete closure of the slide gate achieved the goal of reducing the slide-gate induced mortality for this species. It is unlikely that the 0.1% mortality measured for spring/summer chinook salmon could be reduced further.

Few mechanical or electronic problems were encountered during testing. Of those that did occur, all but one were corrected prior to the end of the test period. The problem not corrected was replacement of the ram on the large slide gate that directs the fish from the small slide gates in the flumes to either the facility sample tank or to the PIT-tag sample tank. The problems encountered last year with this gate were repeated this year. Occasionally, the slide gate did not close completely before the facility sample was taken. This allowed some of the facility sample fish to enter the PIT-tag sample tank during these times, tending to slightly increase the untagged fish per cycle ratio and decrease the facility's hourly estimate of the number of fish moving through the facility. The problem was traced to the oil-ram system which would sometimes plug the exhaust filters with oil, causing a delay in gate closure. At the end of the season a ram system that uses no oil was ordered and will be installed prior to further use of the system.

Overall results of the third year of testing the PIT-tag detection/diversion system indicated that the system functioned well, with higher efficiency, in terms of untagged fish diverted per cycle, than we had originally expected. Furthermore, the efficiency of the system was not impacted by the percentage of steelhead in the population as in past years, and the mortality rate for this species was decreased significantly from the previous year. We believe that the system at Lower Granite Dam is ready for use in research or monitoring programs. It is sufficiently simple to set up and operate for individual researchers to be able to easily fine tune it to accomplish their particular goals.

RECOMMENDATIONS

1. Due to low population abundance and lower than expected recoveries of PIT-tagged smolts at dams, a large-scale study to evaluate transportation of wild yearling chinook salmon smolts should not be planned for the near future.
2. The PIT-tag detection/diversion system at Lower Granite Dam is ready for use for monitoring or research programs.

APPENDIX 2

Scale Analysis Report

ANNUAL PROGRESS REPORT

FISH RESEARCH PROJECT
OREGON

PROJECT TITLE: A determination of the hatchery and wild ratios and selected life history characteristics from scales of transported and non-transported groups of spring chinook and steelhead in the Snake River.

CONTRACT NUMBER: 40ABNF101898

PROJECT PERIOD: May 2, 1991 to December 31, 1991.

Prepared by L.A. Borgerson

Oregon Department of Fish and Wildlife
2501 S.W. First Street
P.O. Box 59
Portland, Oregon 97207

This project was funded by the National Marine Fisheries Service under contract JFT-90-XX-1 with the U.S. Army Corps of Engineers.

CONTENTS

SUMMARY

Objectives for FY 1991

1. Determine the hatchery/wild ratios of transported and non-transported spring and summer chinook salmon from scales of juveniles and adults at Lower Granite Dam.

2. Determine the effects of transport on age at maturity, growth, migration timing, and other life history characteristics from scales of adult spring and summer chinook salmon and steelhead at Lower Granite Dam.

Accomplishments in FY 1991

We read and classified the hatchery or wild rearing origin of 507 spring chinook salmon and 249 summer chinook salmon. We examined scales from 28 spring chinook salmon, 20 summer chinook salmon, and 60 summer steelhead and tested for differences in life history and growth characteristics between transport and control groups.

Findings in FY 1991

We estimated that 20.1% ($\pm$ 4.7%) of the spring chinook salmon and 54.6% ($\pm$7.7%) of the summer chinook salmon passing Lower Granite Dam were wild fish. We found no differences in life history, migration timing, or growth between transported and control groups of chinook salmon. We found that transportation or volitional migration may have differing effects on hatchery and wild summer steelhead.

INTRODUCTION

Since 1975 run sizes of spring and summer chinook salmon in the Snake River have decreased to historical lows with completion of Ice Harbor, Lower Monumental, Little Goose, and Lower Granite Dams. The Columbia Basin Fish and Wildlife Authority has implemented a large-scale transport program in an effort to eliminate mortality of juvenile salmonids caused by dam passage. Although decisions have been made to implement transport at near maximum levels, there is a lack of definitive data on survival benefits of transporting spring chinook salmon (Matthews et al. 1990). Transport benefits for spring chinook salmon have been difficult to assess because of inadequate adult returns and unexplained variability in existing return data. This variation may be due to unknown proportions of hatchery and wild fish in the experimental transport and control samples.

In 1988, the National Marine Fisheries Service (NMFS) initiated a pilot study to assess the feasibility of using PIT tagged wild spring chinook salmon to determine transport benefits to wild fish. However due to low recovery rates (10% of fish marked) at Lower Granite Dam it was apparent that this methodology would be impractical in a large scale study due to the volume of wild fish that would have to be tagged and the high cost of the PIT tags.

Discriminant analysis (DA) of fish scale patterns is a accepted method of identifying hatchery or wild origins of salmon. Between 1978 and 1987, Oregon Department of Fish and Wildlife (ODFW) used DA to correctly classify 85-95% of hatchery and wild coho salmon caught in ocean fisheries off Oregon (Borgerson 1988). Fryer and Schwartzberg (1990) used DA to correctly classify 84-91% of hatchery and wild spring chinook salmon from the Deschutes, Wenatchee, Grand Ronde, and Imnaha rivers. DA will be used as an alternative method to estimate the wild and hatchery composition of the run-at-large as well as fish in experimental transport and control groups for the NMFS transport study.

Benefits of transport have been evaluated in terms of smolt-to-adult survival. Transport may have effects on the life history dynamics of the populations that need to be understood to fully evaluate the benefits of transport programs. It is reasonable to suspect that fish that are transported 320 miles from Lower Granite Dam to below Bonneville Dam in 1-3 days and non-transported fish that migrate volitionally the same distance in 20-60 days may differ in migration, growth and age at maturity. Park (1985) found that steelhead transported from Little Goose and Lower Granite dams returned to hatcheries later that non-transported fish.

Scale analysis will be used to determine if differences exist in growth rates, migration timing, and life history of transported and non-transported (control) groups of spring and summer chinook salmon and summer steelhead.

METHODS

Scale Preparation and Reading

Scale collection for this work involved 3 agencies and 2 tribes. Scales from the mixed stock groups of chinook salmon and steelhead from Lower Granite Dam were collected by NMFS personnel. The known origin scales used to develop the discriminant functions were collected by personnel of Idaho Department of Fish and Game, ODFW, and the Nez Perce and Umatilla tribes. We provided diagrams showing location of the key scale area (Nicholas and Van Dyke 1982) and sample procedures so all collections were sampled by the same methods.

Mixed stock spring and summer chinook salmon from Lower Granite Dam were collected proportionally throughout the run-at-large. We selected the sample size of 550 for both groups so that it would yield a 95% confidence interval that was $\pm$25% of the point estimate when the discriminant function correctly classified 85% of samples and wild fish made up 20-30% of the run. Because the run of summer chinook was less than expected we reduced the samples size to 275 to reduce impact on the fish. All summer steelhead marked for the transport study encountered at Lower Granite Dam were sampled for scales.

We mounted the scales from Lower Granite Dam on gummed cards and made acetate impressions. Scales from other locations were mounted and pressed by the collecting agency. All parties provided location, length, date, presence or absence of mark, and sex data for each sample.

We used an Apple IIc microcomputer, Altec digitizing board, and Scale Reader Program software (Mullen 1984) to measure and record scale measurements. The scale image was enlarged to 88x magnification using a microfiche reader. Measurements were made along a radius 20^{0} to the anterior posterior axis on the ventral side of the scale. We made two groups of measurements; we made extensive measurements in the freshwater zone on all chinook salmon scales used for the hatchery or wild DA (Figure 1). We made a second set of measurements on the portion of the scale that represented early ocean residence and juvenile migration of all chinook salmon and summer steelhead that were marked for the transport study (Figure 2). After reading the scales, measurement data were transferred from the Apple IIc computer to an "IBM compatible" computer for computation of additional variables (Table 1) and final analysis.

Hatchery or Wild Classification of Chinook Salmon

We used discriminant analysis to classify spring and summer chinook salmon by hatchery or wild origin. For discriminant analysis to provide meaningful results the training populations used to develop the function must be representative of the groups within the unknown sample. We "weighted" scales from various streams based on the estimated contribution of fish from that stream to the overall population. For example the wild spring chinook training population was "weighted" so that 1/4 of the samples were from Oregon tributaries and 3/4 were from Idaho tributaries. Components of the hatchery training populations were weighted by release numbers from each hatchery and the survival of the hatchery group.

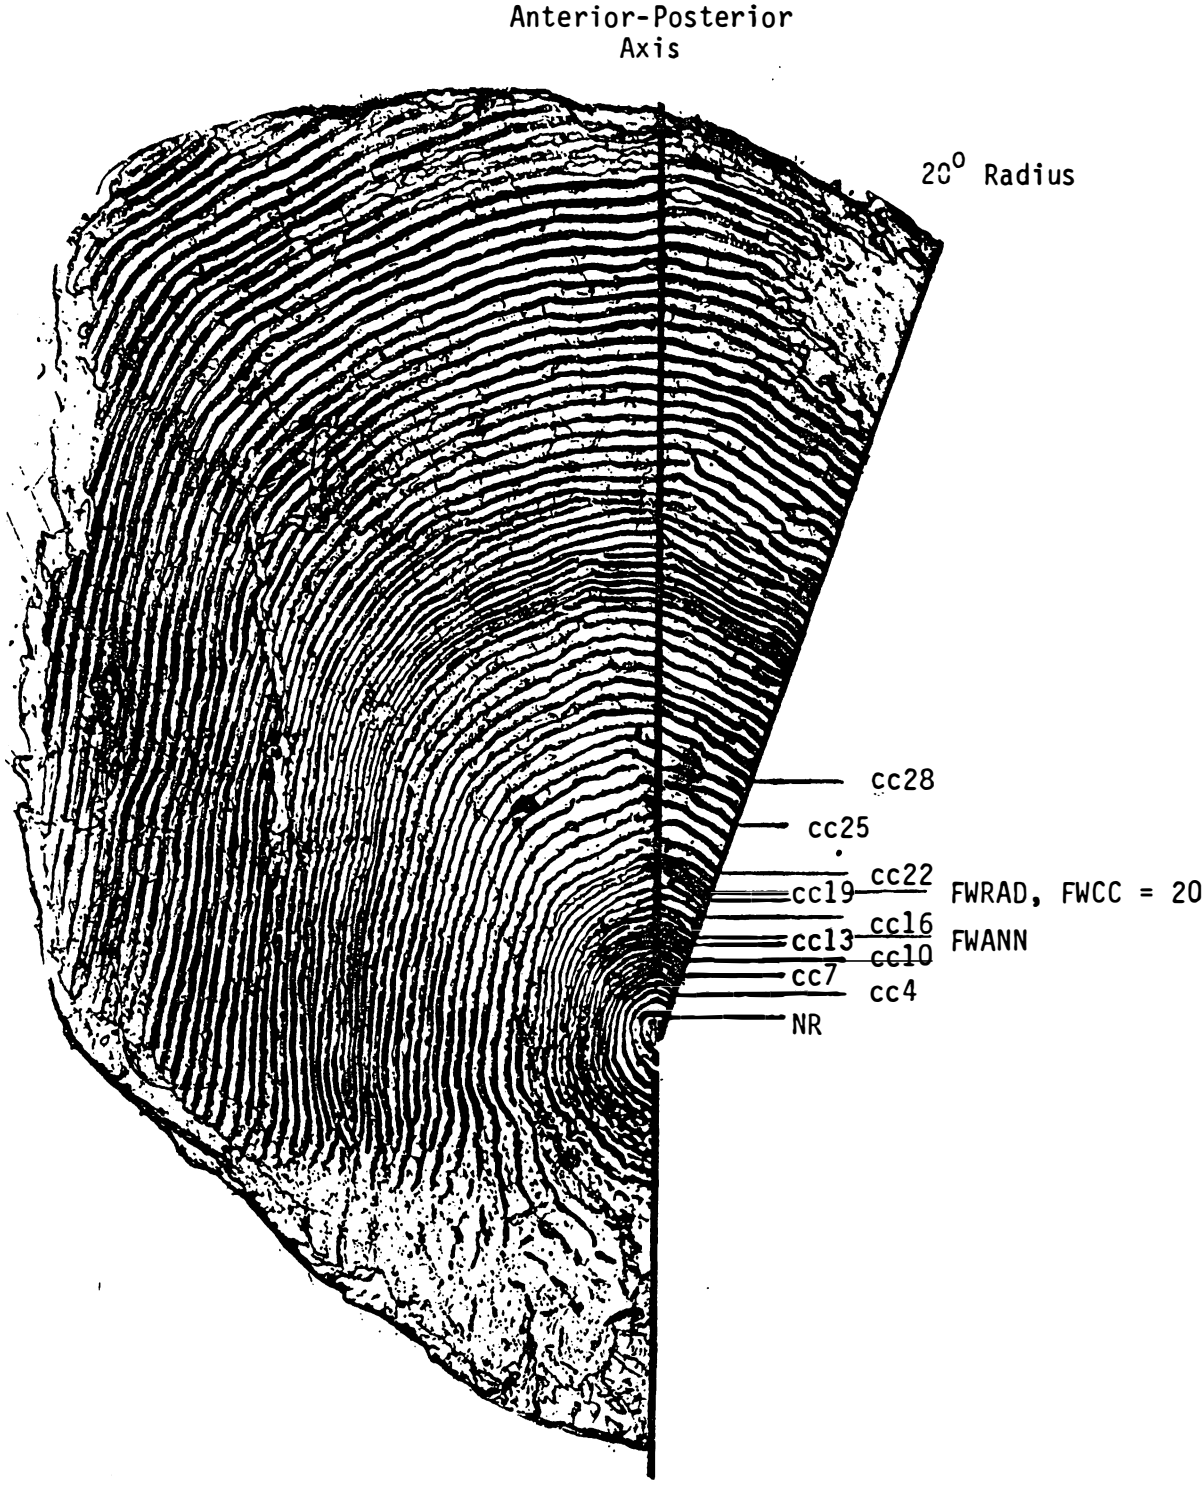

Figure 1. Measurements of scale growth used to discriminate between hatchery and wild chinook salmon. The scale is from a wild spring chinook salmon sampled in Capehorn Creek, tributary to North Fork of the Salmon River. Measurement labels are defined in Table 1.

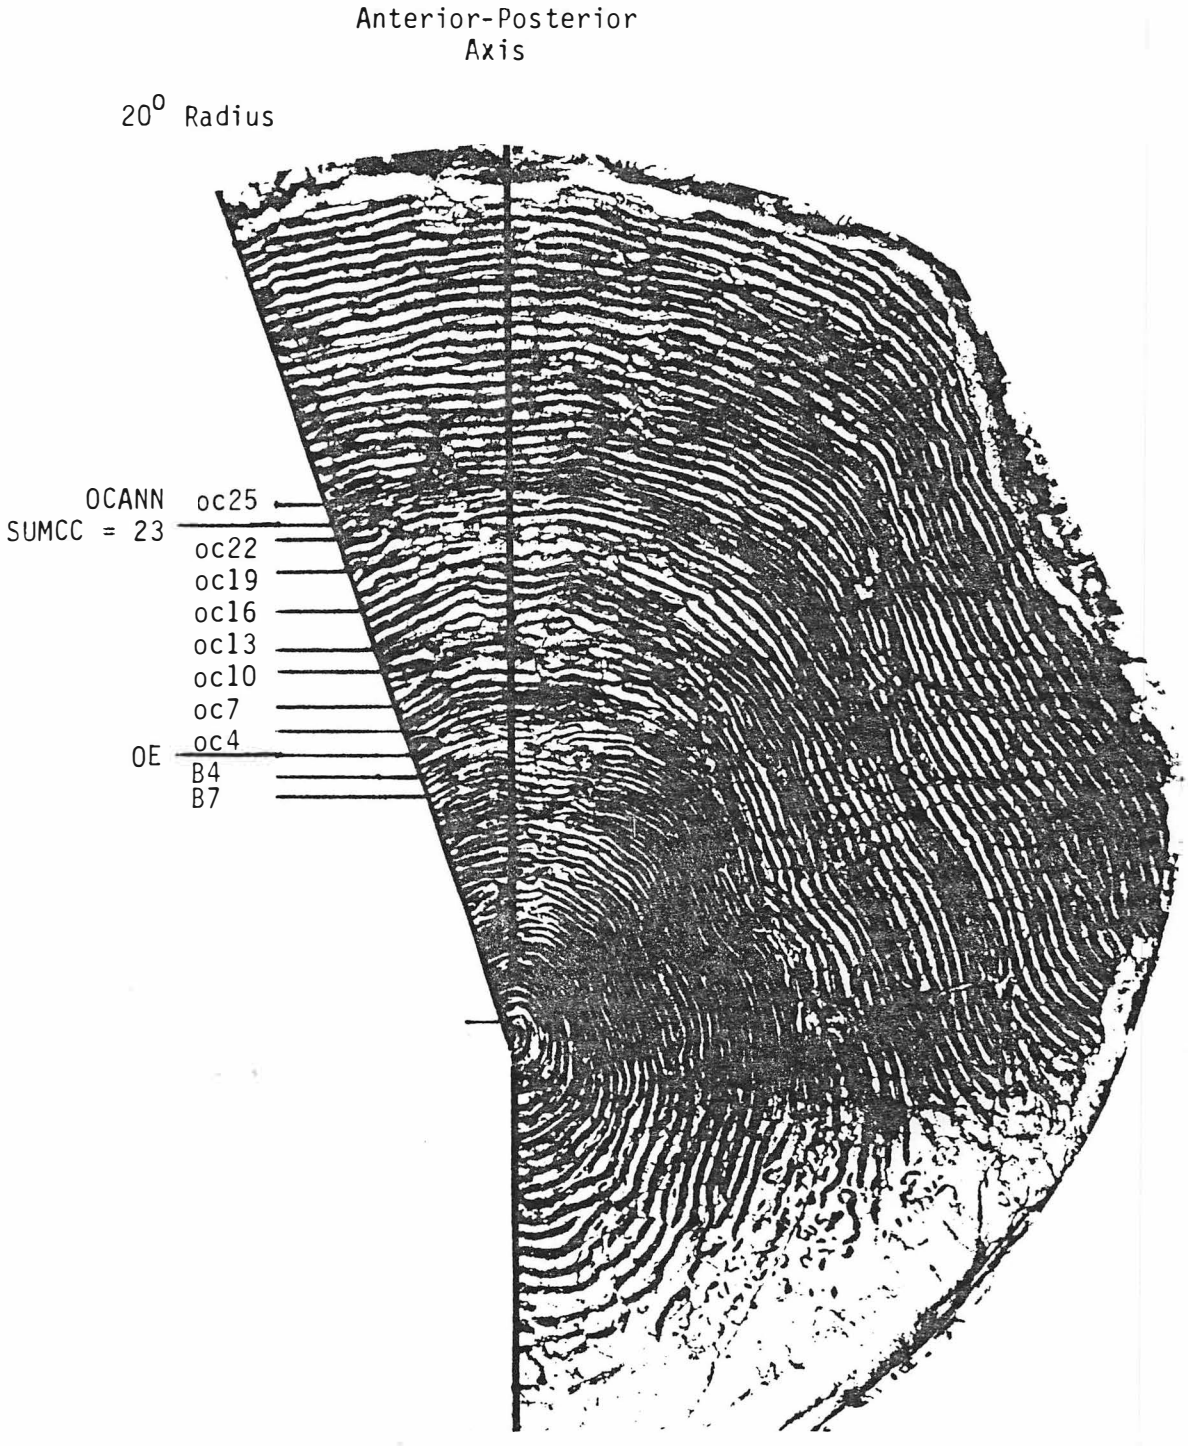

Figure 2. Measurements of scale growth that occurred during juvenile migration and early ocean residence. The scale is from a hatchery reared summer steelhead marked as part of the control group for the transport study. Measurement labels are defined in Table 1.

Table 1. Definition of scale variables read or calculated.

Variable	Definition
Read:	
FWCC	Number of circuli in the freshwater zone.
NR	Radial measurement of the nucleus, also considered circulus 1.
FWANN	Radial measurement to the winter annulus of freshwater zone.
FWRAD, OE	Radial measurement to the last circulus in the freshwater zone.
CC4-CC28	Radial measurements in 3 circuli increments between the fourth and 28th circuli of the freshwater zone.
SUMCC	Number of circuli between OE and the first annulus formed in the ocean.
OCANN	Radial measurement to the first annulus formed in the ocean.
OC4-OC25	Radial measurements in 3 circuli increments between the fourth and 25th circuli of the ocean zone.
B4	Radial measurement to the fourth circulus counted back into the freshwater zone from OE, inclusive.
B7	Radial measurement to the seventh circulus counted back into the freshwater zone from OE, inclusive.
Calculated:	
BW56	Bandwidths 5 and 6, CC19-CC13.
R1D6	Ratio of bandwidths 1 and 6, (CC4-NR)/(CC19-CC16).
JM1	OE - B4.
JM2	B4 - B7.
OR1	OC4 - OE.
OR2	OC7 - OC4.
OR3	OC10 - OC7.
OR4	OC13 - OC10.
OR5	OC16 - OC13.
OR6	OC19 - OC16.
OR7	OC22 - OC19.
OR8	OC25 - OC22.
OET	OCANN-OE.

When we did not have sufficient scales to represent certain groups at the required rate we either substituted scales from another location or, if there were not reasonable substitutes, we reduced the overall size of the training population until the limiting sample was represented at its proper weighting. Initially our goal was to have 150 scales in each training population but after adjusting for locations with low sample size we allowed the training population for wild spring chinook to drop to 88 scales (Table 2).

We developed linear discriminant functions using BMDP Statistical Software 88 Release (Dixon 1988) for spring chinook salmon and summer chinook salmon.

Table 2. Stock composition of training populations used to develop discriminant functions for classifying spring and summer chinook salmon of unknown origin.

Training population, location	Number	Percent
Spring Chinook Salmon		
Hatchery:		
Clearwater	3	2.3
Rapid River	40	30.5
Red River	6	4.6
Powell	7	5.3
Sawtooth	27	20.6
Dworshak	1	0.8
Lookingglass[a]	27	20.6
Lookingglass	20	15.3
	131	100.0
Wild:		
North Fork Salmon	53	60.2
Selway	2	2.3
Salmon	11	12.5
Grand Ronde	22	25.0
	88	100.0
Summer Chinook Salmon		
Hatchery:		
McCall	35	35.0
Pahsimeroi	37	37.0
Lookingglass	28	28.0
	100	100.0
Wild:		
South Fork Salmon	80	66.7
Imnaha	40	33.3
	120	100.0

[a] Samples used as substitutes for unavailable samples from Dworshak and Kooskia hatcheries.

Both functions classified the fish according to hatchery or wild origin. Variables were added to or removed from the function in a step-wise method based on their F values. The spring chinook function contained 2 variables (FWANN and BW56) and the summer chinook function contained 3 variables (FWANN, FWRAD, and R1D6). For both functions the variable FWANN, representing fish size at the end of the winter in freshwater, was the first variable selected and was very powerful at discriminating between hatchery and wild fish.

Ideally, we would have tested the classification ability of our functions with additional sets of known origin samples but that was not possible. Instead, we estimated correct classification using the jackknife method (Efron 1982), provided by BMDP Statistical Software, as well as bootstrap and cross-validation methods (Efron and Tibshirani 1991). Results from the three methods differed by only 0.4% for spring chinook salmon, with the cross validation method yielding the most conservative estimate. Classification rates for both functions were estimated by cross-validation (Table 3).

After the mixed stock samples were classified, we corrected the results for misclassification and calculated confidence intervals using the methods of Worlund and Fredin (1962). Within the mixed stock samples were a few fish that had been marked for the transport study. We noted the percent wild within the marked transport and control groups but did not correct the estimate or calculate confidence intervals for these small subsamples.

Table 3. Two-way classification matrixes for the hatchery and wild groups of spring and summer chinook salmon.

Function, Correct group	Percent Correct	Number of fish classified into each group: Wild	Hatchery
Spring chinook salmon			
Wild	86.4	76	12
Hatchery	92.4	10	121
Overall correct classification:	90.0		
Summer chinook salmon			
Wild	91.7	110	10
Hatchery	89.0	11	89
Overall correct classification:	90.5		

Differences in Age Composition, Ocean Growth Rate, and Migration Timing Between Hatchery and Wild Fish Belonging to Experimental Transport or Control Groups

We used two-way analysis of variance on scale measurements representing ocean entrance timing and growth during juvenile migration and early ocean residence to test for significant differences ($p \leq .05$) between hatchery or wild fish that were transported or used as controls during the transport study. Chinook salmon were included in either the hatchery or wild group based on the results of the discriminant analysis. Steelhead were identified as hatchery fish by having clipped fins. All steelhead released from hatcheries in the Snake River system are fin clipped. Steelhead with no clipped fins were assumed to be wild. Chinook salmon and summer steelhead were identified as belonging to experimental transport and control groups by various freeze brands (Matthews et al. 1990).

To represent growth that occurred during early ocean residence we used measurements of circuli bands radiating out from the ocean entrance check. To represent growth that occurred in the Snake and Columbia rivers during migration, we measured two bands of circuli that immediately preceded the ocean entrance check (Figure 2). Depending on how quickly a fish migrated, these river bands may include growth from freshwater residence as well as migration.

We used the distance between the first winter annulus formed in the ocean and the ocean entrance check to index the time of ocean entrance. We assumed that the winter annulus was formed at the same time of the year for all fish so if the distance between the ocean entrance check and the annulus is large the fish had entered the ocean "early". A small distance would indicate "late" ocean entrance.

We determined the age of each fish by counting winter annuli. We used a contingency table to compare the age compositions of transport and control groups of summer steelhead but did not statistically test the age compositions of spring or summer chinook because we felt the samples sizes were too small.

RESULTS

We read 507 scales from the spring chinook salmon run passing Lower Granite Dam and estimated that 20.1% ($\pm$4.7%) were wild fish. Likewise we read 249 scales from summer chinook salmon and estimated that 54.6% ($\pm$7.7%) were wild fish. Within our samples from the spring chinook salmon run-at-large were 28 samples marked by the transport study. Of the samples marked as belonging to the control group 44.4% were classified as wild while 20.0% of the transported fish were classified as wild. There were 20 summer chinook salmon recovered from the transport study; 50.0% of control fish (n=2) and 77.8% of transported fish were classified as wild.

We found no differences in growth rates or migration timing between transported or control groups of combined spring and summer chinook salmon (Table 4). We did find significant differences between wild and hatchery chinook salmon in one variable representing growth just after ocean entrance and in the variable used as an index of ocean entrance time. Our results indicate that wild fish may enter the ocean later than hatchery fish.

Table 4. Two-way analysis of variance and group means for scale variables representing growth during juvenile migration (JM) and early ocean residence (OR), and ocean entrance timing (OET) for adult spring and summer chinook salmon from the transport study sampled at Lower Granite Dam in 1991.

Variable name	Means				Significant differences ($p < .05$)		
	Wild		Hatchery				Type x origin
	Transport	Control	Transport	Control	Type	Origin	interaction
JM1	58.9	59.8	60.4	57.4			
JM2	55.2	57.8	55.9	46.1			
OR1	87.5	95.0	100.5	101.1			
OR2	101.9	104.6	121.4	112.0		X	
OR3	100.5	109.4	109.6	105.9			
OR4	99.8	108.0	96.6	108.0			
OR5	103.9	105.0	107.1	105.9			
OR6	102.5	102.6	105.1	109.1			
OR7	99.2	97.0	99.6	102.2			
OR8	96.6	94.3	101.7	101.6			
OET	705.4	704.0	724.4	777.1		X	
Sample size	21	5	17	9			

We found significant differences between hatchery and wild summer steelhead in variables representing ocean entrance time and growth during river migration and early ocean (Table 5). Wild steelhead tended to have larger growth measurements. Our results also indicate that transportation may have different effects on time of ocean entrance for hatchery and wild summer steelhead.

We found no significant differences between the age compositions of transported and control groups of summer steelhead (X^2=6.795, p=.2363). Age compositions for spring and summer chinook salmon and summer steelhead are given in Table 6.

PLANS FOR 1992

In 1992 we plan to repeat all work accomplished in 1991. In addition we plan to determine the hatchery and wild composition of the juvenile populations of spring and summer chinook salmon for comparison to the hatchery and wild composition of the returning adults.

Table 5. Two-way analysis of variance and group means for scale variables representing growth during juvenile migration (JM) and early ocean residence (OR), and ocean entrance timing (OET) for adult summer steelhead from the transport study sampled at Lower Granite Dam in 1991.

Variable name	Means				Significant differences ($p < .05$)		
	Wild		Hatchery				
	Transport	Control	Transport	Control	Type	Origin	Type x origin interaction
JM1	68.7	63.7	64.3	65.0			
JM2	55.7	55.8	67.5	62.5		X	
OR1	92.0	96.0	84.6	97.9			
OR3	114.8	128.7	95.7	103.2		X	
OR4	104.3	126.7	94.6	99.8	X	X	
OR5	97.8	112.8	99.3	99.3			
OR6	113.7	114.8	99.2	86.4		X	
OR7	100.3	110.7	93.0	78.3		X	
OR8	92.4	99.8	81.8	66.2		X	
OET	757.3	960.7	684.3	580.1		X	X
Sample size	6	6	27	21			

Table 6. Age composition of summer steelhead, spring chinook salmon and summer chinook salmon from the transport study sampled at Lower Granite Dam in 1991.

Total age	Life history[a] (Freshwater/Marine)	Transport		Control	
		Number	Percent	Number	Percent
Summer steelhead					
3	1/1	8	22.2	4	13.3
4	1/2	16	44.4	18	60.0
4	1/3	5	13.9	0	0
4	2/1	2	5.6	1	3.3
5	2/2	3	8.3	5	16.7
6	3/2	2	5.6	2	6.7
Spring chinook salmon					
3	1/1	1	6.3	0	0.0
4	1/2	15	93.7	11	91.7
5	1/3	0	0.0	1	8.3
Summer chinook salmon					
3	1/1	7	38.9	0	0.0
4	1/2	9	50.0	2	100.0
5	1/3	2	11.1	0	0.0

[a] Number of freshwater annuli/number of ocean annuli.

ACKNOWLEDGMENTS

I would like to thank R. Kanani Bowden and Robert Mikus for their scale reading expertise; Ron Boyce and Gene Matthews for their support; and Jerry Harmon and crew, Rich Carmichael, and crew, Peter Lofy, Paul Kucera, and Dave Cannamela and crew for collecting the scales used in this work.
